

# Analytical Results for the Community Environmental Monitoring Program (CEMP) Air Sampling Network—Third Quarter CY2010

The CEMP air-sampling network is designed to monitor and collect radioactive airborne particles from NTS and non-NTS related activities, as well as background environmental sources. This report is compiled by the Desert Research Institute (DRI) and summarizes the results from the analysis of the air samples collected by CEMP station managers as part of the community environmental monitoring program.

In general, the CEMP air-sampling network is comprised of 29 continuously operating environmental sampling stations. A total of 27 stations are equipped with a low volume air sampler/totalizer configuration to collect particulate radionuclides on glass fiber filter paper. Ideally, the samples are collected on a bi-weekly basis with a target collection time of 336 hours (two weeks). The samplers are calibrated on a monthly basis by DRI to maintain a collection rate of 1.75 cfm (@ STP). All relevant information such as collection times, variations in flow rate, actual flow volumes, power outages, and other information documenting the integrity of the sample are recorded by the station managers. This allows for the proper interpretation of the analytical results. The air filters are analyzed by a commercial laboratory for gross alpha/beta activity as well as by high-resolution gamma spectrometry. The filters are composited on a quarterly basis (13 weeks) for gamma spectroscopy analysis only after the gross alpha/beta analyses have been completed.

In the U.S., the principle reporting unit for the measurement of radioactivity in the atmospheric environment is pCi/m<sup>3</sup> (picocuries per cubic meter). DRI receives its data from the lab as microcuries per filter. DRI converts the laboratory data unit of measurement to pCi/m<sup>3</sup> for the ease in comparison of data. The data for the environmental thermoluminescent dosimeter (TLD) is reported in milliroentgens (mR).

A summary of the third quarter CY2010 analytical results for gross alpha and beta analyses are found in Tables 1 and 2. These tables document the minimum, maximum, and average values for each of the 27 air-sampling network stations. The last column shows the average annual value from the previous year (CY2009) for comparison purposes. Overall the gross alpha results for the third quarter of CY2010 reflect similar values to previous quarters. These data remain consistent with the average CY2009 analyses used for comparison, especially when analytical error is considered. The third quarter CY2010 beta results are also consistent with previous results.

The third quarter gamma results for CY2010 are shown in Table 3. All of the samples were gamma spectrum negligible (i.e. gamma emitting radionuclides were not detected) with the exception of Beryllium (Be)-7 and occasionally Lead (Pb)-210, both naturally occurring elements of the atmospheric and geologic environment, respectively. Overall, these data are consistent with previous analytical results.

The TLD results for the third quarter of CY2010 are shown in Table 4. Overall, the results display similar values to the previous quarters of the last calendar year. The 2009 pressurized ion chamber, or PIC exposure rate and TLD data are also provided for comparison. As with historical data, TLD values are commonly lower than the PIC

results. The overall estimated annual exposure based on the third quarter shows consistent agreement with CY2009.

DRI welcomes and encourages input from the station managers regarding the content of the CEMP quarterly reports. If there is anything you feel we could provide to help you interpret the data or enable you to explain the information to someone in your community not familiar with the program, please let us know.
