DOE/NV/25946--2566

Nevada National Security Site Environmental Report 2014

This report was prepared for:

U.S. Department of Energy
National Nuclear Security Administration
Nevada Field Office

By:

National Security Technologies, LLC
Las Vegas, Nevada

September 2015

Compiled by **Cathy Wills, Editor**

Work performed under contract number:

DE-AC52-06NA25946

THIS PAGE LEFT INTENTIONALLY BLANK

Executive Summary

This report was prepared to meet the information needs of the public and the requirements and guidelines of the U.S. Department of Energy (DOE) for annual site environmental reports. It was prepared by National Security Technologies, LLC (NSTec), for the U.S. Department of Energy, National Nuclear Security Administration Nevada Field Office (NNSA/NFO) (formerly designated as the Nevada Site Office [NNSA/NSO]). The new field office designation occurred in March 2013. Published reports cited in this 2014 report, therefore, may bear the name or authorship of NNSA/NSO. This and previous years' reports, called Annual Site Environmental Reports (ASERs), Nevada Test Site Environmental Reports (NTSERs), and, beginning in 2010, Nevada National Security Site Environmental Reports (NNSSERs), are posted on the NNSA/NFO website at <http://www.nv.energy.gov/library/publications/aser.aspx>.

Purpose and Scope of the NNSSER

This NNSSER was prepared to satisfy DOE Order DOE O 231.1B, "Environment, Safety and Health Reporting." Its purpose is to (1) report compliance status with environmental standards and requirements, (2) present results of environmental monitoring of radiological and nonradiological effluents, (3) report estimated radiological doses to the public from releases of radioactive material, (4) summarize environmental incidents of noncompliance and actions taken in response to them, (5) describe the NNSA/NFO Environmental Management System and characterize its performance, and (6) highlight significant environmental programs and efforts.

This NNSSER summarizes data and compliance status for calendar year 2014 at the Nevada National Security Site (NNSS) (formerly the Nevada Test Site) and its two support facilities, the North Las Vegas Facility (NLVF) and the Remote Sensing Laboratory–Nellis (RSL–Nellis). It also addresses environmental restoration (ER) projects conducted at the Tonopah Test Range (TTR) and the Nevada Test and Training Range (NTTR). Through a Memorandum of Agreement, NNSA/NFO is responsible for the oversight of these ER projects, and the Sandia Field Office of NNSA (NNSA/SFO) has oversight of all other TTR and NTTR activities. NNSA/SFO produces the TTR annual environmental report, which is available at <http://www.sandia.gov/news/publications/environmental/index.html>.

Major Site Programs and Facilities

NNSA/NFO directs the management and operation of the NNSS and six sites across the nation. The six sites include two in Nevada (NLVF and RSL–Nellis) and four in other states (RSL–Andrews in Maryland, Livermore Operations in California, Los Alamos Operations in New Mexico, and Special Technologies Laboratory in California). Los Alamos, Lawrence Livermore, and Sandia National Laboratories are the principal organizations that sponsor and implement the nuclear weapons programs at the NNSS. NSTec is the current Management and Operating contractor accountable for the successful execution of work and ensuring that work is performed in compliance with environmental regulations. The six sites all provide support to enhance the NNSS as a location for weapons experimentation and nuclear test readiness.

The three major NNSS missions include National Security/Defense, Environmental Management, and Nondefense. The major programs that support these missions are Stockpile Stewardship and Management, Nonproliferation and Counterterrorism, Nuclear Emergency Response, Strategic Partnership Projects, Environmental Restoration, Waste Management, Conservation and Renewable Energy, Other Research and Development, and Infrastructure. The major facilities that support the programs include the U1a Facility, Big Explosives Experimental Facility (BEEF), Device Assembly Facility, Dense Plasma Focus Facility, Joint Actinide Shock Physics Experimental Research Facility, Radiological/Nuclear Countermeasures Test and Evaluation Complex, Nonproliferation Test and Evaluation Complex (NPTEC), Radiological/Nuclear Weapons of Mass Destruction Incident Exercise Site (known as the T-1 Site), Area 5 Radioactive Waste Management Complex (RWMC), and the Area 3 Radioactive Waste Management Site (RWMS).

Other Key Environmental Initiatives

In addition to the environmental restoration efforts to clean up legacy contamination from historical nuclear testing activities, NNSA/NFO pursues several other environmental key initiatives. They are components of the Nondefense mission of NNSA/NFO to prevent pollution, minimize waste generation, conserve water, advance energy efficiency, reduce fossil fuel use, pursue renewable energy sources, and support the federal goals within all of these areas promulgated through executive orders and DOE orders. These initiatives are pursued through the Energy Management Program and the Pollution Prevention and Waste Minimization (P2/WM) Program discussed below.

Environmental Performance Measures Programs

During the conduct of the major programs mentioned above, NNSA/NFO complies with applicable environmental and public health protection regulations and strives to manage the NNSS as a unique and valuable national resource. To identify NNSS environmental initiatives, NNSA/NFO implements an Integrated Safety Management System (ISMS) and an Environmental Management System (EMS). The ISMS is designed to ensure the systematic integration of environment, safety, and health concerns into management and work practices so that NNSS missions are accomplished safely and in a manner that protects the environment. NNSA/NFO oversees ISMS implementation through the Integrated Safety Management Council.

The EMS is designed to incorporate concern for environmental performance throughout all site programs and activities, with the ultimate goal being continual reduction of program impacts on the environment. The NNSS attained International Organization for Standardization (ISO) 14001 certification for its EMS in 2008. The ISO 14001 certifying organization, Lloyd's Register Quality Assurance (LRQA) recertified the EMS for another 3 years in June 2014. LRQA conducts semi-annual surveillances on focused portions of the EMS, and findings and recommendations are tracked in the companywide issues tracking system, caWeb. In addition, internal independent audits, management assessments, and compliance evaluations are conducted annually to promote continual improvement. In January 2014, the LRQA conducted the semi-annual surveillance. In April 2014, it conducted the EMS recertification surveillance. No issues were found, and the EMS was recertified in 2014 for another 3-year period. An internal EMS audit was conducted in November and throughout 2014, a total of 7 internal management assessments and 74 compliance evaluations were conducted on numerous activities related to environmental compliance. Two procedural non-compliance issues were found and immediately corrected.

Each fiscal year (FY) (October 1 through September 30), an Environmental Working Group (EWG) helps determine what EMS objectives and targets will be worked on and tracked to address specific environmental aspects of NNSA/NFO operations. Many of the EMS objectives and targets support DOE in attaining their complex-wide site sustainability goals, which are published annually in a DOE Strategic Sustainability Performance Plan (SSPP) available at <http://energy.gov/lm/downloads/2014-doe-strategic-sustainability-performance-plan>. In 2014, the EWG identified two objectives. One was to find new opportunities to increase the diversion of solid wastes from the NNSS landfill, and one was to identify biobased and environmentally preferable products that could be purchased as replacements for non-biobased and less preferable products. Both 2014 objectives were met and will continue to be implemented. The FY 2014 EMS objectives are summarized in Section 3.3.2 of Chapter 3.

The 2014 Facility EMS Annual Report Data for the NNSS was entered into the DOE Headquarters EMS database on the www.FedCenter.gov website. The report includes a scorecard section that is a series of questions regarding a site's EMS effectiveness in meeting the objectives of federal EMS directives. The NNSS scored "green" (the highest score) in 2014.

Energy Management Program (EMP) - The EMP advances energy efficiency, water conservation, and the use of solar and other renewable energy sources at the NNSS, NLVF, and RSL-Nellis. This program implements initiatives that support DOE in attaining their site sustainability goals related to energy and water efficiency, which are identified in the annual DOE SSPP. The EMP also prepares annually an NNSA/NFO Site Sustainability Plan (SSP), which describes all of the DOE SSPP goals, NNSA/NFO's current performance status towards reaching each goal, and planned actions to meet each goal. As of the end of 2014, NNSA/NFO has already met 8 of the 11 2014 DOE long-term goals related to reducing energy, water, and petroleum fuel use. Progress towards meeting all of DOE's 2014 SSPP goals is summarized in Table 3-1 of Chapter 3.

Pollution Prevention and Waste Minimization (P2/WM) Program - The P2/WM Program promotes activities that reduce or eliminate waste generation, reduce the release of pollutants to the environment, and reduce the use of Class I ozone-depleting substances. This program supports DOE in attaining their complex-wide site sustainability goals related to P2/WM activities. In 2014, 35% of non-hazardous solid waste and 43% of construction waste was diverted from disposal in NNSS landfills through re-use and recycling. The DOE SSPP target goals are 50% and 55%, respectively, by the end of FY 2015. These goals may not be reached on the NNSS without additional funding.

Environmental Awards

NNSA/NFO earned three environmental awards in 2014 (Section 3.8). They included a DOE Federal Energy and Water Management Award for NNSA/NFO's Alternative Fuel Vehicle (AFV) Management Program, an NNSA Environmental Stewardship Award in the Green Buildings Category for energy use reductions at Warehouse 23-160, and one DOE Sustainability Award for overall progress toward attaining several DOE sustainability goals.

The NNSS was the only DOE recipient of the DOE Federal Energy and Water Management Award in 2014. The award-winning NNSA/NFO AFV Management Program was responsible for increasing the use of renewable fuels on the NNSS by 195% in FY 2013 and by 164% in FY 2014 when compared to the FY 2005 baseline. This increase was achieved through the construction of two ethanol (E-85) alternative fuel capable service stations and implementing an innovative fuel lock-out program that identifies flex fuel vehicles and prioritizes the use of E-85.

NSS Warehouse 23-160 in Mercury earned the Green Buildings Category NNSA Environmental Stewardship Award due to a series of projects conducted from 2009 through 2014 that dramatically reduced the cost of heating the warehouse by approximately \$58,000 a year. Energy conservation initiatives included the installation of lighting and heating controls and a Clean Burn System comprised of four Clean Burn furnaces, which use recycled oil for fuel, and four large energy-efficient fans. Numerous other energy, water, and solid waste conservation measures were initiated in 2014 at this warehouse.

In February 2015, it was announced that NNSS was selected to receive a 2014 DOE Sustainability Award to recognize NNSS's noteworthy progress in effective energy, water, and vehicle fleet management that has resulted in meeting many of the DOE sustainability goals ahead of schedule.

Compliance

One measure of the effectiveness of the EMS is the degree of compliance with applicable environmental laws, regulations, and policies that protect the environment and the public from the effects of NNSA/NFO operations. In 2014, NNSA/NFO complied with all federal statutes, as shown below.

Federal Statute	What it Covers	2014 Status
Radiation Protection		
DOE O 458.1, "Radiation Protection of the Public and the Environment" (and its predecessor of the same name, DOE O 5400.5)	Measuring radioactivity in the environment and estimating radiological dose to the public due to NNSA/NFO activities	Radiological monitoring was conducted by NNSA/NFO at 18 onsite air stations, 7 offsite and 12 onsite groundwater sources, and 110 stations measuring direct gamma radiation. Fourteen plant and 9 small mammal samples from 3 study locations and their 2 control locations; 18 opportunistic samples of large game animals; and 13 mountain lion scat samples were collected to monitor biota. The total dose to the maximally exposed individual (MEI) from all exposure pathways due to NNSA/NFO activities was estimated to be 3.25 millirems per year (mrem/yr), well below the DOE limit of 100 mrem/yr. The majority of this dose (3.23 mrem/yr) is estimated to come from the ingestion of game animals.
Atomic Energy Act (through compliance with DOE O 435.1, "Radioactive Waste Management")	Management of low-level waste (LLW) and mixed low-level waste (MLLW) generated or disposed on site	1,272,901 cubic feet of radioactive wastes including LLW, MLLW, and non-radioactive classified items were received and disposed on site. All amounts of disposed radiological wastes for permitted disposal units were within permit limits. All vadose zone and ground-water monitoring continued to verify that disposed LLW and MLLW are not migrating to groundwater or threatening biota or the environment.

Federal Statute	What it Covers	2014 Status
Air Quality and Protection		
<p>Clean Air Act: National Emission Standards for Hazardous Air Pollutants (NESHAP) National Ambient Air Quality Standards (NAAQS) New Source Performance Standards (NSPS) Stratospheric Ozone Protection</p>	<p>Air quality and emissions into the air from facility operations</p>	<p>There are no major sources of criteria air pollutants or hazardous air pollutants at the NNSS, NLVF, or RSL-Nellis. Nonradiological air emissions from all permitted equipment/facilities were below permit emission and opacity limits.</p> <p>One Notice of Alleged Violation was issued to NNSA/NFO by the State for an NNSS emergency generator that turned on automatically and operated more than its allowed 100 hours per year.</p> <p>The 18 onsite continuous air sampling stations detected man-made radionuclides at levels comparable to previous years and well below the regulatory dose limit for air emissions to the public of 10 mrem/yr. The estimated dose from all 2014 NNSS air emissions to the MEI is 0.02 mrem/yr.</p>
Water Quality and Protection		
<p>Clean Water Act (CWA) Safe Drinking Water Act (SDWA)</p>	<p>Water quality and effluent discharges from facility operations</p> <p>Quality of drinking water</p>	<p>All required maintenance, monitoring, and reporting were conducted for permitted wastewater systems and monitoring wells. All domestic and industrial wastewater systems and groundwater monitoring well samples were within permit limits for regulated water contaminants and water chemistry parameters.</p> <p>Pumped groundwater samples at the NLVF were all within National Pollutant Discharge Elimination System (NPDES) permit limits. NNSS operations do not require any NPDES permits.</p> <p>All three permitted public water systems (PWSs) on the NNSS met federal and state water quality standards with one exception: the Area 25 PWS water sample had aluminum and iron above their state permitted levels.</p>
Waste and Hazardous Materials Management and Environmental Restoration		
<p>Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA)/Superfund Amendments and Reauthorization Act (SARA) Federal Facility Agreement and Consent Order (FFACO) Resource Conservation and Recovery Act (RCRA)</p>	<p>Cleanup of waste sites containing hazardous substances</p> <p>Cleanup of waste sites containing hazardous substances</p> <p>Generation, management, and/or disposal of HW and MLLW and cleanup of inactive, historical waste sites</p>	<p>No hazardous waste (HW) cleanup operations on the NNSS are regulated under CERCLA or SARA; they are regulated under the Resource Conservation and Recovery Act (RCRA) instead. The requirements of CERCLA applicable to the NNSS pertain to an emergency response program for hazardous substance releases (see Emergency Planning and Community Right-to-Know Act [EPCRA] below) and to how state laws concerning the removal and remediation of hazardous substances apply to federal facilities (specifically, implementation of the Federal Facility Agreement and Consent Order [FFACO]).</p> <p>All 2014 milestones established under the FFACO with the State of Nevada were met for conducting corrective actions and closures of historical contaminated sites called corrective action sites (CASs). A total of 16 Soils CASs were closed in accordance with State-approved corrective action plans.</p> <p>A total of 1,338 tons of MLLW were disposed in Cell 18, 0.75 tons of MLLW were shipped for offsite disposal, 8.94 tons of HW and 2.41 tons of polychlorinated biphenyl (PCB) waste were received for onsite storage at the Hazardous Waste Storage Unit (HWSU), and 7.67 tons of HW and 2.18 tons of PCB waste were shipped for offsite disposal from the HWSU, all in accordance with state permits. An additional 10.83 tons of HW were shipped directly off site from Hazardous Waste Accumulation Areas. No waste explosive ordnance were detonated on site.</p>

Federal Statute	What it Covers	2014 Status
Waste and Hazardous Materials Management and Environmental Restoration (continued)		
Resource Conservation and Recovery Act (RCRA) (continued)		Semiannual water samples from three groundwater monitoring wells at the Area 5 RWMC confirmed that buried MLLW remains contained. All vadose zone monitoring and post-closure inspections of historical RCRA closure sites confirmed the sites' integrity to contain HW.
National Environmental Policy Act (NEPA)	Projects are evaluated for environmental impacts	NNSA/NFO evaluated 31 projects. A Record of Decision for the final <i>Site-Wide Environmental Impact Statement for the Nevada National Security Site and Offsite Locations in Nevada</i> was published in 2014.
Toxic Substances Control Act (TSCA)	Management and disposal of PCBs	Thirteen drums of PCB-contaminated materials were shipped off site to permitted disposal and treatment facilities. Their contents included fluorescent light ballasts.
Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA)	Storage and use of pesticides and herbicides	Only one restricted-use herbicide was used in 2014 along with other non-restricted-use pesticides/herbicides. All chemicals were applied by State of Nevada-certified personnel. Storage and use of pesticides were in compliance with federal and state regulations.
Emergency Planning and Community Right-to-Know Act (EPCRA)	The public's right to know about chemicals released into the community	No accidental or unplanned release of an extremely hazardous substance occurred at the NNSS, NLVF, or RSL-Nellis in 2014. The chemical inventory for NNSS, NLVF, and RSL-Nellis was updated and submitted to the State of Nevada. As part of routine activities and cleanup operations, reportable quantities of lead, mercury, and PCBs were released at the NNSS in 2014 and reported to the U.S. Environmental Protection Agency. Releases included onsite disposal, offsite disposal, and offsite recycling and totaled 81,472 pounds (lb) for lead, 410 lb for mercury, and 31 lb for PCBs.
Other Environmental Statutes		
Endangered Species Act (ESA)	Threatened or endangered species of plants and animals	Field surveys for 15 proposed projects in desert tortoise habitat and 3 projects in other habitats on the NNSS were conducted; 5.14 acres of tortoise habitat were disturbed. No tortoises were harmed at or displaced from project sites. No tortoises were accidentally killed by vehicles on paved roads, and 13 were moved off of roads out of harm's way. All actions were in compliance with the U.S. Fish and Wildlife Service's requirements for work conducted in desert tortoise habitat.
National Historic Preservation Act (NHPA)	Identifying and preserving historic properties	NNSA/NFO maintained compliance with the NHPA. Archival research for 39 proposed projects was conducted, and 556 acres were surveyed for nine of the projects; 18 historic sites and 1 site containing evidence/artifacts of both historic and prehistoric occupations were identified.
Migratory Bird Treaty Act (MBTA)	Protecting migratory birds, nests, and eggs from harm	During biological surveys for proposed projects, no migratory bird nests, eggs, or young were found in harm's way. However, 7 accidental bird deaths due to human activities were documented.

Occurrences and Unplanned Releases

No unplanned airborne releases and no unplanned releases of radioactive liquids occurred from the NNSS, NLVF, or RSL-Nellis in 2014. There were three reportable environmental occurrences in 2014, all on the NNSS: radiological contamination was found at a lined well sump in Area 19 outside of a posted area, an emergency generator in Area 6 turned itself on and operated more than its allowed limit of hours under non-emergency conditions in violation of the NNSS state air permit, and five drums of LLW were received at the Area 5 RWMS from the State of Tennessee that were later determined to contain chromium, a RCRA hazardous waste. The

drums are currently buried in a non-RCRA regulated LLW disposal cell. Proper notifications and corrective actions were taken or are pending. These three reportable occurrences are summarized in Table 2-12 of Chapter 2. Twenty-two other minor spills occurred at the NNSS, none of which met regulatory agency reporting criteria. They consisted of small-volume releases either to containment areas or to other surfaces and did not exceed a reportable quantity. All these minor spills were cleaned up.

Radiation Dose to the Public

Background Gamma Radiation – Mean background gamma radiation exposure rates on the NNSS are estimated using 11 thermoluminescent dosimeter (TLD) stations located away from radiologically contaminated sites. The average mean exposure rate among these 11 stations in 2014 was 114 milliroentgen per year (mR/yr) and ranged from 65 to 163 mR/yr (Section 6.3.1). The Desert Research Institute (DRI) used TLDs at offsite locations in 2014, and these measurements ranged from 72 mR/yr at St. George, Utah, to 158 mR/yr at Sarcobatus Flat, Nevada (Section 7.1.5).

Public Dose from Direct Radiation – Areas accessible to the public had direct external gamma radiation exposure rates in 2014 comparable to natural background rates. The TLD locations on the west and north sides of the parking area at Gate 100, the NNSS entrance gate, had estimated annual mean exposures of 85 and 61 mR/yr, respectively, similar to the range of background exposures observed on the NNSS (Section 6.3.2). Military or other personnel on the NTTR could be exposed to direct radiation from legacy sites on Frenchman Lake playa. A TLD location in the playa and near the NNSS boundary with NTTR had an estimated annual exposure of 271 mR (Section 6.3.2). This represents an above-background exposure of 108 to 206 mrem/yr (depending on which background radiation value is subtracted), which would exceed the 100 mrem/yr dose limit if a member of the public were to reside at this location. However, there are no living quarters or full-time personnel in that area. Because the nearest resident does not live in close proximity of the site, there is no dose contribution from external gamma radiation from NNSS operations to the public.

Public Dose from Drinking Water – Man-made radionuclides from past nuclear testing have not been detected in offsite drinking water supply wells or springs in the past or during 2014 (Section 5.1.2). Therefore, there is no dose contribution from drinking water to the public due to NNSS operations.

Public Dose from Inhalation – The radiation dose limit to the public via the air transport pathway is established by NESHAP under the Clean Air Act to be 10 mrem/yr. The U.S. Environmental Protection Agency (EPA), Region IX, has approved the use of six air sampling stations on the NNSS to verify compliance with this dose limit. The following radionuclides were detected at four or more of the critical receptor samplers: americium-241 (^{241}Am), plutonium-238 (^{238}Pu), plutonium-239+240 ($^{239+240}\text{Pu}$), uranium-233+234 ($^{233+234}\text{U}$), uranium-235+236 ($^{235+236}\text{U}$), uranium-238 (^{238}U), and tritium (^3H) (Section 4.1.4). Concentrations of these radionuclides at each of the stations indicated that the NESHAP dose limit to the public was not exceeded. The Schooner station in the far northwest corner of the NNSS experienced the highest concentrations of radioactive air emissions (Section 4.1.5). The Gate 510 sampler, however, is the closest station to a public receptor (3.5 kilometers [km] [2.2 miles (mi)]). The estimated effective dose equivalent from air emissions for a hypothetical individual living year-round at the Gate 510 sampler would be 0.02 mrem/yr.

Public Dose from Ingestion of Radionuclides in Game Animals – Game animals and small mammals (used as models for small game animals) are analyzed for their radionuclide content to estimate the dose to the public who might consume these animals if they were to move off the NNSS and be harvested by hunters. In 2014, tissue samples were collected from two jackrabbits from Plutonium Valley; one cottontail from the Plutonium Valley control site; six composited small mammal samples (ground squirrels and kangaroo rats) from the Area 3 RWMS, the Area 5 RWMS, and the RWMS control site; and two pronghorn antelope and eighteen mule deer (sixteen of which were killed by a radio-collared mountain lion). An individual who consumes one mule deer having elevated radionuclide concentrations similar to one of the 18 deer sampled in 2014 that had the highest radionuclide body burden, may receive an estimated 3.23 mrem/yr dose (Section 9.1.1.2).

Public Dose from All Pathways – The radiation dose limit to the general public via all possible transport pathways (over and above background dose) established by DOE is 100 mrem/yr. The public dose from all pathways in 2014 was estimated to be 3.25 mrem/yr. This is 3.25% of the 100 mrem/yr dose limit and about 0.90% of the total dose the MEI receives from natural background radiation (360 mrem/yr) (Section 9.1.3).

Monitoring of Radiological Releases into Air

Offsite – An offsite radiological air monitoring program is run by the Community Environmental Monitoring Program (CEMP) and is coordinated by DRI of the Nevada System of Higher Education under contract with NNSA/NFO (Chapter 7). It is a non-regulatory public informational and outreach program, and its purpose is to provide monitoring for radionuclides that might be released from the NNSS. A network of 24 CEMP stations monitor gross alpha and beta radioactivity in airborne particulates using low-volume particulate air samplers, penetrating gamma radiation using TLDs, gamma radiation exposure rates using pressurized ion chamber (PIC) detectors, and meteorological parameters using automated weather instrumentation. The stations are located in selected towns and communities of southern Nevada, southeastern California, and southwestern Utah. DRI also manages four stations having only automated weather instrumentation that are located on private ranches.

As in previous years, no airborne radioactivity related to historical or current NNSS operations was detected in any of the samples from the CEMP particulate air samplers during 2014. TLD and PIC detectors measure gamma radiation from all sources: natural background radiation from cosmic and terrestrial sources and man-made sources. The offsite TLD and PIC results attributable to NNSS operations remained consistent with previous years' background levels and are well within background levels observed in other parts of the United States.

Onsite – Radionuclide emissions on the NNSS are from the following sources: (1) evaporation of tritiated water from containment ponds; (2) diffusion of tritiated water vapor from soil at the Area 3 RWMS, the Area 5 RWMC, and historical surface or near-surface nuclear device test locations (particularly Sedan and Schooner Craters); (3) resuspension of contaminated soil at historical surface or near-surface nuclear device test locations; and (4) release of radionuclides from current operations. A network of 20 air sampling stations and a network of 110 TLDs on the NNSS were used to monitor onsite radioactive emissions.

Total radiological atmospheric releases from the NNSS in curies (Ci) for 2014 (Section 4.1.8) are shown in the table below. An estimated 0.0017 Ci of tritium were released at the NLVF.

³ H	⁸⁵ Kr	Noble Gases (T _{1/2} * <40 days)	Short-Lived Fission and Activation Products (T _{1/2} <3 hr)	Fission and Activation Products (T _{1/2} >3 hr)	Total Radio- iodine	Total Radio- strontium	Plutonium	Other Actinides
878	0	177	4,749	0.02	0	0	0.050 (²³⁸ Pu) 0.29 (²³⁹⁺²⁴⁰ Pu)	0.047 (²⁴¹ Am)

* T_{1/2} = half-life

The mean tritium concentration in air samples from across all tritium sampling stations was 8.34×10^{-6} picocuries per milliliter (pCi/mL) and ranged from below detection to 352.06×10^{-6} pCi/mL at the Schooner crater station (Section 4.1.4.5). The mean annual exposure rate for direct gamma radiation at the 41 TLDs located near active projects, working personnel, and public access areas was 114 mR, the same as the mean for the 11 background radiation stations (Section 6.3).

Monitoring of Radionuclides in Water

Offsite – An offsite monitoring program for tritium in groundwater sampled from community or private wells is run by the CEMP and coordinated by DRI (Chapter 7). In 2014, the CEMP sampled groundwater for tritium in one community well from each of four communities: Tecopa (in California) and Amargosa Valley, Beatty, and Sarcobatus Flat (all in Nevada) (Section 7.2). Beginning in 2014, DRI limited monitoring to groundwater wells in CEMP communities located within the regional groundwater flow system that are downgradient or perceived to be downgradient of the NNSS in order to increase efficiency and relevancy of the program while simultaneously decreasing costs. Tritium concentrations in the four wells were all below analytical detection limits (Section 7.2.3).

NNSA/NFO's offsite groundwater sampling network includes eight NTTR Characterization wells (wells used to support the objectives of groundwater characterization and of modeling the flow of man-made radionuclides

downgradient from historical underground nuclear tests), two NTTR Early Detection wells (wells that are the first wells downgradient of an underground nuclear test or a Source/Plume well, but which currently contain no radiological contaminants above background levels), one NTTR Distal well (a well farther downgradient from Early Detection wells), and eight Community water sources that are on Bureau of Land Management (BLM) or private lands. In 2014, NNSA/NFO sampled three of the Characterization wells, the two Early Detection wells, and two of the Community wells on BLM land for tritium. Tritium was detected at the Characterization wells ER-EC-11 (at elevated levels [16,100 pCi/L]) and ER-EC-12 (at very low levels [4.2 pCi/L]), as in previous years at both of these wells (Section 5.1.3.1). Tritium was also found at low levels (237 pCi/L) in the Early Detection well PM-3, confirming the presence of tritium in this well detected in 2011, 2012, and 2013 (Section 5.1.3.3). No tritium was detected in the Community wells. Hydrogeologic data west of the NNSS are sparse, and thus groundwater flow predictions are uncertain. Sample results collected to date, along with future sampling of the NTTR wells and modeling will be used to further develop flow and transport contamination models of the area.

Offsite water monitoring conducted in 2014 and over the past decade continues to verify that there are no man-made radionuclides from NNSS underground contamination areas in any public or private water supply wells or springs being monitored.

Onsite – NNSA/NFO’s onsite groundwater sampling network includes 20 Characterization wells, 20 Source/Plume wells (wells that contain contaminated groundwater verified to originate from NNSS underground nuclear testing and that are within the detonation region or are downgradient of the detonation at the plume edge), 8 Early Detection wells, and 6 Distal wells. NNSA/NFO also samples annually six permitted NNSS public water system (PWS) wells and five onsite locations called Compliance wells/surface waters, which are monitored to demonstrate compliance with specific federal/state regulations or NNSS permits.

In 2014, NNSA/NFO sampled six Characterization, three Source/Plume, two Early Detection, and three Distal wells on the NNSS for tritium. Of these, the three sampled Characterization wells in Area 20 and the three sampled Source/Plume wells in Area 5 had elevated tritium levels, as they have in previous years (Sections 5.1.3.1 and 5.1.3.2). Along with data from the offsite wells in the groundwater sampling network, data from all onsite wells are being used to aid in the development of a long-term closure monitoring network for each of the five known areas of groundwater contamination on the NNSS. The monitoring well networks will provide an early warning and allow for protective measures to be taken if contaminants are detected. The network will also comply with all corrective actions established under the FFAO with the State of Nevada (Section 11.1).

In 2014, the six NNSS PWS wells were sampled for tritium and for gross alpha and gross beta radioactivity. None of the PWS wells had detectable concentrations of tritium (Section 5.1.3.6). Detectable gross alpha and gross beta radioactivity found in many of the PWS well samples likely represents the presence of naturally occurring radionuclides, and none exceeded their EPA allowable limits for drinking water.

In 2014, the five onsite Compliance wells/surface waters were sampled for tritium and for gross alpha and gross beta radioactivity. All water samples were within their permit limits for these analytes (Section 5.1.3.7). Groundwater and drilling fluids discharged from wells monitored in 2014 were also sampled and found to be below the fluid management criteria limits for selected radiological and non-radiological parameters (Section 5.1.3.7.3).

Release of Property Containing Residual Radioactive Material

No property can be released from the NNSS unless the amount of residual radioactivity on the property is less than the authorized limits, which are consistent with DOE O 458.1. Items proposed for unrestricted release are either surveyed (physically sampled), or a process knowledge evaluation is conducted to verify that the material has not been exposed to radioactive material or beams of radiation capable of generating radioactive material. In 2014, 390 pieces of laboratory equipment, 5 vehicles, and 6 pieces of heavy equipment were released off site to the public (Section 9.1.5). In addition, over 400 tons of non-hazardous waste (e.g., scrap metal) and over 40,000 tons of waste containing lead (e.g., lead acid batteries) were released to vendors for recycling or reuse. No released items had residual radioactivity in excess of the authorized limits.

Onsite Nonradiological Releases into Air

The release of air pollutants is regulated on the NNSS under a Class II air quality operating permit. Class II permits are issued for minor sources where annual emissions must not exceed 100 tons of any one criteria pollutant, 10 tons of any one of the 189 hazardous air pollutants (HAPs), or 25 tons of any combination of HAPs. Criteria pollutants include sulfur dioxide, nitrogen oxides (NO_x), carbon monoxide, particulate matter, and volatile organic compounds. The NNSS facilities regulated by the permit include (1) approximately 14 facilities and 131 pieces of equipment throughout the NNSS, (2) NPTEC, (3) Site-Wide Chemical Release Areas, (4) the BEEF, (5) the Explosives Ordnance Disposal Unit, and (6) Explosives Activities Sites in Areas 5, 14, 25, 26, and 27.

An estimated 9.53 tons of criteria air pollutants were released on the NNSS in 2014 (Section 4.2.3). The majority was NO_x from diesel generators. Total HAPs emissions from permitted operations was 0.03 tons. Lead air emissions from non-permitted activities, such as weapons use, are reported to the EPA, and this quantity in 2014 was 2.5 lb (Section 12.3). No emission limits for any criteria air pollutants or HAPs were exceeded.

One chemical release test series was conducted in 2014, consisting of numerous small releases of chemicals over a 10-day period at the Area 5 NPTEC facility and at Port Gaston in Area 6 (Section 4.2.6). The majority of the chemicals released were neither HAPs nor criteria pollutants, and no permit limits were exceeded. No ecological monitoring was performed because each test posed a very low level of risk to the environment and biota. In 2014, explosives were detonated at the BEEF and Port Gaston, and no permit limits were exceeded.

Onsite Nonradiological Releases into Water

There are no liquid discharges to navigable waters, offsite surface water drainage systems, or publicly owned treatment works resulting from operations on the NNSS. Therefore, no Clean Water Act NPDES permits are required for operations on the NNSS. Industrial discharges on the NNSS are limited to three operating sewage lagoon systems, the Area 6 Yucca Lake, the Area 23 Mercury, and the Area 6 Device Assembly Facility (DAF) systems. Sewage systems are monitored quarterly for influent quality. Influent water samples are analyzed for 5-day biological oxygen demand, total suspended solids, and pH. In 2014, all results were within the permit limits (Section 5.2.3.1). E Tunnel effluent, sampled for nonradiological contaminants (mainly metals), had levels of contaminants below permit limits (Section 5.2.4).

Nonradiological Releases into Air and Water at NLVF and RSL-Nellis

Sources of air pollutants at the NLVF and RSL-Nellis are regulated by permits from the Clark County Department of Air Quality. The regulated sources of air emissions include an abrasive blaster, an aluminum sander, a spray paint booth, diesel and gasoline generators, fire pumps, cooling towers, and boilers. The calculated total emissions of criteria pollutants at NLVF and RSL-Nellis were 1.08 and 13.29 tons per year, respectively (Appendix A, Sections A.1.1 and A.2.1). HAPs calculated emissions at RSL-Nellis were 0.03 tons per year. HAPs emissions are minor and are not regulated at the NLVF.

Water discharges at the NLVF are regulated by a permit with the City of North Las Vegas (CNLV) for sewer discharges and by an NPDES discharge permit issued by the Nevada Division of Environmental Protection for dewatering operations to control rising groundwater levels that surround the facility. The NPDES permit authorizes the discharge of pumped groundwater to the groundwater of the state via percolation and to the Las Vegas Wash via the CNLV storm drain system. Sewer discharge waters at the NLVF are no longer required to be sampled and analyzed for various contaminants (Appendix A, Section A.1.2.1). In 2014, the discharge from pumped groundwater at the NLVF did not exceed NPDES permit limits, and quarterly, annual, and biennial water samples of the pumped groundwater analyzed in 2014 had water quality measurements that were all below permit limits (Appendix A, Section A.1.2.2). No wastewater quality monitoring is required by the Clark County Water Reclamation District (CCWRD) at RSL-Nellis. Instead, a Zero Discharge Form is submitted annually to the CCWRD.

Acknowledgements

The Ecological and Environmental Monitoring (E&EM) group of National Security Technologies, LLC (NSTec), is responsible for producing this document for the U.S. Department of Energy, National Nuclear Security Administration Nevada Field Office (NNSA/NFO). Each year, the production of the annual Nevada National Security Site Environmental Report (NNSER) requires the knowledge, skill, experience, and cooperation of many people and organizations.

Contributing Subject Matter Experts

More than 30 individuals who are subject matter experts from across multiple organizations authored, co-authored, or contributed information to the chapters within this NNSER. They are thanked and acknowledged for their support and are identified at the beginning of each chapter.

Contributing Organizations

NSTec

Multiple departments and groups within NSTec provided subject matter experts across multiple departments who contributed text and data on the annual activities related to onsite radiological and non-radiological monitoring of air, water, and biota; radiological dose assessments; waste management; environmental restoration; groundwater protection; hazardous materials management; ecological monitoring; site sustainability; and occurrence reporting.

Desert Research Institute (DRI)

The Water Resources division of DRI authored Chapters 7 and 17, reporting on their offsite radiological monitoring of air and groundwater within communities surrounding the NNS and on their data quality assurance program. The Cultural Resources division of DRI authored Chapter 14, summarizing their annual activities managing cultural resources on the NNS.

Navarro-Intera, LLC (N-I)

N-I provided data and discussion in Chapters 5 and 11 regarding the design, sampling, and analysis results of the NNS integrated groundwater monitoring program that addresses the legacy contamination of historical nuclear underground test areas (UGTAs). Also in Chapter 11, N-I provided summary information of their characterization and remediation work towards State-approved closure of UGTA, industrial, and soil corrective action sites, and post-closure monitoring of soil corrective action sites.

National Oceanic and Atmospheric Administration Air Resources Laboratory, Special Operations and Research Division (ARL/SORD)

ARL/SORD provided summary descriptions of the NNS climate that are included in *Attachment A: Site Description* on the compact disc of this report.

U.S. Geological Survey (USGS)

The USGS provided discussion and data in Chapter 13 regarding their monitoring of NNS groundwater levels and usage.

EnviroStat

Charles Davis of EnviroStat provided the statistical analyses, interpretation, and graphical presentations of the environmental radiological monitoring data collected by E&EM.

E&EM Support Staff

The following individuals within NSTec E&EM are responsible for the numerous tasks that are integral to the collection, quality assurance, and quality control of much of the environmental data provided in this NNSER.

Terrence P. Sonnenburg coordinated field sampling operations and assisted with field sampling

Elizabeth Burns was responsible for radiological monitoring data verification, validation, and review; quality assurance oversight; administration of the data management system; and assisted with field sampling

Martin D. Cavanaugh and Matthew O. Weaver conducted field sampling

Catherine D. Castaneda was responsible for sample management supporting the sub-contracting of environmental analytical services

Lynn N. Jaussi managed laboratory operations for sample screening and processing

Theodore J. Redding is the E&EM manager and provided oversight for radiological monitoring data verification, validation, and review; quality assurance; and sample management

NSTec Report Production and Distribution Support Personnel

The following individuals were responsible for improving the quality, appearance, and timely production and distribution of this NNSER.

Ashley Burns worked with all the authors to produce the high-quality GIS-generated maps and figures.

Shirley Burns provided a thorough review of this document to ensure spelling, format, grammar, references, tables, figures, acronyms, table of contents, etc., were all in order and assisted with creating the final electronic files of the report for Internet posting and burning onto compact disc.

Katina Loo is the document's graphic artist and desktop publisher who designed the NNSER cover, CD label, and the layout of the NNSER Summary.

Pablo Mendez, Jeff Li, and Mark Shaw produced high-quality hard copies and compact discs of the NNSER and the NNSER Summary under a tight production schedule.

Chapter 1: Introduction and Helpful Information

1.1 Site Location

The U.S. Department of Energy, National Nuclear Security Administration Nevada Field Office (NNSA/NFO) (designated as the Nevada Site Office [NNSA/NSO] prior to March 2013) directs the management and operation of the Nevada National Security Site (NNSS). The NNSS is located in Nye County in south-central Nevada (Figure 1-1). The southeast corner of the NNSS is about 88 kilometers (km) (55 miles [mi]) northwest of the center of Las Vegas in Clark County. By highway, it is about 105 km (65 mi) from the center of Las Vegas to Mercury. Located at the southern end of the NNSS, Mercury is the main base camp for worker housing and administrative operations for the NNSS.

The NNSS encompasses about 3,522 square kilometers (km²) (1,360 square miles [mi²]) based on the most recent land survey. It varies from 46 to 56 km (28 to 35 mi) in width from west to east and from 64 to 88 km (40 to 55 mi) from north to south. The NNSS is surrounded on all sides by federal lands (Figure 1-1). It is bordered on the west and north by the Nevada Test and Training Range (NTTR), on the east by an area used by both the NTTR and the Desert National Wildlife Range, and on the south and southwest by Bureau of Land Management lands. The combination of the NTTR and the NNSS represents one of the largest unpopulated land areas in the United States, comprising some 14,200 km² (5,470 mi²).

1.2 Environmental Setting

The NNSS is located in the southern part of the Great Basin, the northern-most sub-province of the Basin and Range Physiographic Province. The NNSS terrain is typical of much of the Basin and Range Physiographic Province, characterized by generally north-south trending mountain ranges and intervening valleys. These mountain ranges and valleys, however, are modified on the NNSS by very large volcanic calderas (Figure 1-2). The principal valleys are Frenchman Flat, Yucca Flat, and Jackass Flats (Figure 1-2). Both Yucca and Frenchman Flat are topographically closed and contain dry lake beds, or playas, at their lowest elevations. Jackass Flats is topographically open, and surface water from this basin flows off the NNSS via the Fortymile Wash. The dominant highlands are Pahute Mesa and Rainier Mesa (high volcanic plateaus), Timber Mountain (a resurgent dome of the Timber Mountain caldera complex), and Shoshone Mountain. In general, the slopes of the highland areas are steep and dissected, and the slopes in the lowland areas are gentle and less eroded. The lowest elevation on the NNSS is 823 meters (m) (2,700 feet [ft]) in Jackass Flats in the southeast, and the highest elevation is 2,341 m (7,680 ft) on Rainier Mesa in the north-central region.

The topography of the NNSS has been altered by historical U.S. Department of Energy (DOE) actions, particularly underground nuclear testing. The principal effect of testing has been the creation of numerous collapse sinks (craters) in Yucca Flat basin and fewer craters on Pahute and Rainier Mesas. Shallow detonations that created surface disruptions were also performed during Project Plowshare to determine the potential uses of nuclear devices for large-scale excavation.

The reader is directed to *Attachment A: Site Description*, a file on the compact disc of this report, where the geology, hydrology, climatology, ecology, and cultural resources of the NNSS are described.

1.3 Site History

The history of the NNSS, as well as its current missions, directs the focus and design of the environmental monitoring and surveillance activities on and near the site. Between 1940 and 1950, the area known as the NNSS was under the jurisdiction of Nellis Air Force Base and was part of the Nellis Bombing and Gunnery Range. The site was established in 1950 to be the primary location for testing the nation's nuclear explosive devices. It was

Figure 1-1. NNSS vicinity map

Figure 1-2. Major topographic features and calderas of the NNSS

named the Nevada Test Site (NTS) in 1951 and supported nuclear testing from 1951 to 1992. The types of tests conducted during this period are briefly described below. On August 23, 2010, the NTS was named the NNSS to reflect the diversity of nuclear, energy, and homeland security activities now conducted at the site. Nuclear experiments conducted at the NNSS are currently limited to subcritical experiments.

Atmospheric Tests – Tests conducted through the 1950s were predominantly atmospheric tests. They involved a nuclear explosive device detonated while either on the ground surface, on a steel tower, suspended from tethered balloons, dropped from an aircraft, or placed on a rocket. Several tests were categorized as “safety experiments” and “storage-transportation tests,” involving the destruction of a nuclear device with non-nuclear explosives. Some of these tests resulted in the dispersion of plutonium in the test vicinity. One of these test areas lies just north of the NNSS boundary at the south end of the NTTR, and four others are at the north end of the NTTR.

Underground Tests – The first underground test, a cratering test, was conducted in 1951. The first totally contained underground test was in 1957. Testing was discontinued during a bilateral moratorium that began October 31, 1958, but was resumed in September 1961 after the Union of Soviet Socialist Republics resumed nuclear testing. After late 1962, nearly all tests were conducted in sealed vertical shafts drilled into Yucca Flat and Pahute Mesa or in horizontal tunnels mined into Rainier Mesa. From 1951 to 1992, a total of 828 underground nuclear tests were conducted at the NNSS. Approximately one-third of them were detonated near or in the saturated zone (see Glossary, Appendix B).

Cratering Tests – Five earth-cratering (shallow-burial) tests were conducted from 1962 through 1968 as part of the Plowshare Program that explored peaceful uses of nuclear explosives. The first and highest yield Plowshare crater test, Sedan (U.S. Public Health Service, 1963), was detonated at the northern end of Yucca Flat on the NNSS. The second-highest yield crater test was Schooner, located in the northwest corner of the NNSS. From these tests, mixed fission products, tritium, and plutonium were entrained in the soil ejected from the craters and deposited on the ground surrounding the craters.

Other Tests – Other nuclear-related experiments at the NNSS have included the BREN [Bare Reactor Experiment–Nevada] series in the early 1960s conducted in Area 4. These tests were performed with a 14-million electron volt neutron generator mounted on a 465 m (1,527 ft) steel tower to produce neutron and gamma radiation for the purpose of estimating the radiation doses received by survivors of Hiroshima and Nagasaki. The tower was moved in 1966 to Area 25 and used for conducting Operation HENRE [High-Energy Neutron Reactions Experiment], jointly funded by the U.S. Department of Defense (DoD) and the Atomic Energy Commission (AEC) to provide information for the AEC’s Division of Biology and Medicine. From 1959 through 1973, a series of open-air nuclear reactor, nuclear engine, and nuclear furnace tests was conducted in Area 25, and a series of tests with a nuclear ramjet engine was conducted in Area 26. Erosion of metal cladding on the reactor fuel released some fuel particles that caused negligible deposition of radionuclides on the ground. Most of the radiation released from these tests was gaseous in the form of radio-iodines, radio-xenons, and radio-kryptons.

Fact sheets on many of the historical tests mentioned above can be found at <http://www.nv.energy.gov/library/factsheets.aspx>. All nuclear device tests are listed in *United States Nuclear Tests, July 1945 through September 1992* (U.S. Department of Energy, Nevada Operations Office 2000).

1.4 Site Mission

NNSA/NFO directs the facility management and program operations at the NNSS, North Las Vegas Facility (NLVF), and Remote Sensing Laboratory–Nellis (RSL–Nellis) in Nevada and directs selected operations at four sites outside of Nevada that include RSL–Andrews in Maryland, Livermore Operations in California, Los Alamos Operations in New Mexico, and the Special Technologies Laboratory in California. Los Alamos National Laboratory, Lawrence Livermore National Laboratory, and Sandia National Laboratories are the principal organizations that sponsor and implement the nuclear weapons programs at the NNSS. National Security Technologies, LLC, is the current Management and Operations contractor accountable for the successful execution of work and ensuring that work is performed in compliance with environmental regulations. The three major NNSS missions include National Security/Defense, Environmental Management, and Nondefense. The programs that support these missions are listed in the text box below.

NNSS Missions and Programs

National Security/Defense Missions

Stockpile Stewardship and Management Program – Conducts high-hazard operations in support of defense-related nuclear and national security experiments and maintains the capability to resume underground nuclear weapons testing, if directed.

Nuclear Emergency Response, Nonproliferation, and Counterterrorism Programs – Provides support facilities, training facilities, and capabilities for government agencies involved in emergency response, nonproliferation technology development, national security technology development, and counterterrorism activities.

Strategic Partnership Projects – Provides support facilities and capabilities for other DOE programs and federal agencies/organizations involved in defense-related activities (formerly known as the Work for Others Program).

Environmental Management Missions

Environmental Restoration Program – Characterizes and remediates the environmental legacy of nuclear weapons and other testing at NNSS and NTTR locations, and develops and deploys technologies that enhance environmental restoration.

Waste Management Program – Manages and safely disposes of low-level waste, mixed low-level waste, and classified waste/matter received from DOE- and DoD-approved facilities throughout the U.S. and wastes generated in Nevada by NNSA/NFO. Safely manages and characterizes hazardous and transuranic wastes for offsite disposal.

Nondefense Missions

General Site Support and Infrastructure Program – Maintains the buildings, roads, utilities, and facilities required to support all NNSS programs and to provide a safe environment for NNSS workers.

Conservation and Renewable Energy Programs – Operates the pollution prevention program and supports renewable energy and conservation initiatives at the NNSS.

Other Research and Development – Provides support facilities and NNSS access to universities and organizations conducting environmental and other research unique to the regional setting.

1.5 Primary Facilities and Activities

The NNSS facilities or centers that support the National Security/Defense missions include the U1a Complex, Big Explosives Experimental Facility, Device Assembly Facility (DAF), Dense Plasma Focus Facility (located within the Los Alamos Technical Facility), Joint Actinide Shock Physics Experimental Research (JASPER) Facility, Nonproliferation Test and Evaluation Complex (NPTEC), the National Criticality Experiments Research Center (located within the DAF), the Radiological/Nuclear Countermeasures Test and Evaluation Complex (RNCTEC), and the Radiological/Nuclear Weapons of Mass Destruction Incident Exercise Site (known as the T-1 Site). NNSS facilities that support Environmental Management missions include the currently active Area 5 Radioactive Waste Management Complex (RWMC) and the Area 3 Radioactive Waste Management Site (RWMS), which is in cold standby (Figure 1-3).

The primary NNSS activity in 2014 was helping to ensure that the U.S. stockpile of nuclear weapons remains safe and reliable. Other 2014 NNSS activities included weapons of mass destruction first responder training; the controlled release of hazardous material at NPTEC; remediation of legacy contamination sites; processing of waste destined for the Waste Isolation Pilot Plant in Carlsbad, New Mexico, or the Idaho National Laboratory in Idaho Falls, Idaho; and disposal of low-level and mixed low-level radioactive waste. Land use by each of the NNSS missions occurs within designated zones (Figure 1-4).

1.6 Scope of Environmental Report

This report summarizes data and the compliance status of the NNSA/NFO environmental protection and monitoring programs for calendar year 2014 at the NNSS and at its two support facilities, the NLVF and RSL-Nellis. This report also addresses environmental restoration (ER) projects conducted at the Tonopah Test Range (TTR) (see Figure 1-1).

Figure 1-3. NNSS operational areas, principal facilities, and past nuclear testing areas

Figure 1-4. NNSA land-use map

Through a Memorandum of Agreement, NNSA/NFO is responsible for the oversight of TTR ER projects, and the U.S. Department of Energy, National Nuclear Security Administration Sandia Field Office (NNSA/SFO) has oversight of all other TTR activities. NNSA/SFO produces the TTR annual site environmental reports, which are posted at <http://www.sandia.gov/news/publications/environmental/index.html>.

1.7 Populations near the NNSS

The population of the area surrounding the NNSS (see Figure 1-1) is predominantly rural. Population estimates for Nevada communities are provided by the Nevada State Demographer’s Office (2015). The most recent population estimate for Nye County is 45,456, and the largest Nye County community is Pahrump (37,626), located approximately 80 km (50 mi) south of the NNSS Control Point facility (near the center of the NNSS). Other Nye County communities include Tonopah (2,578), Amargosa (1,426), Beatty (975), Round Mountain (846), Gabbs (245), and Manhattan (133). Lincoln County to the east of the NNSS includes a few small communities including Caliente (1,056), Pioche (784), Panaca (797), and Alamo (578). Clark County, southeast of the NNSS, is the major population center of Nevada and has an estimated population of 2,069,450. The total annual population estimate for all Nevada counties, cities, and unincorporated towns is 2,843,301.

The Mojave Desert of California, which includes Death Valley National Park, lies along the southwestern border of Nevada. This area is still predominantly rural; however, tourism at Death Valley National Park swells the population to more than 5,000 on any particular day during holiday periods when the weather is mild.

The extreme southwestern region of Utah is more developed than the adjacent portion of Nevada. The latest population estimates for Utah communities are for 2013 taken from the U.S. Census Bureau (2015) of the U.S. Department of Commerce. Southern Utah’s largest community is St. George, located 220 km (137 mi) east of the NNSS, with an estimated population of 76,817. The next largest town, Cedar City, is located 280 km (174 mi) east-northeast of the NNSS and has an estimated population of 29,162.

The northwestern region of Arizona is mostly rangeland except for that portion in the Lake Mead recreation area. In addition, several small communities lie along the Colorado River. The largest towns in the area are Bullhead City, 165 km (103 mi) south-southeast of the NNSS, with an estimated population of 39,465, and Kingman, 280 km (174 mi) southeast of the NNSS, with an estimated population of 28,620 (Arizona Department of Administration 2015).

1.8 Understanding Data in this Report

1.8.1 Scientific Notation

Scientific notation is used in this report to express very large or very small numbers. A very small number is expressed with a negative exponent, for example 2.0×10^{-5} . To convert this number from scientific notation to a more traditional number, the decimal point must be moved to the left by the number of places equal to the exponent (5 in this case). The number thus becomes 0.00002.

Very large numbers are expressed in scientific notation with a positive exponent. The decimal point should be moved to the right by the number of places equal to the exponent. The number 1,000,000,000 could be presented in scientific notation as 1.0×10^9 .

1.8.2 Unit Prefixes

Units for very small and very large numbers are commonly expressed with a prefix. The prefix signifies the amount of the given unit. For example, the prefix k, or kilo-, means 1,000 of a given unit. Thus 1 kg (kilogram) is 1,000 g (grams). Other prefixes used in this report are listed in Table 1-1.

Table 1-1. Unit prefixes

Prefix	Abbreviation	Meaning
mega-	M	1,000,000 (1×10^6)
kilo-	k	1,000 (1×10^3)
centi-	c	0.01 (1×10^{-2})
milli-	m	0.001 (1×10^{-3})
micro-	μ	0.000001 (1×10^{-6})
nano-	n	0.000000001 (1×10^{-9})
pico-	p	0.000000000001 (1×10^{-12})

1.8.3 Units of Radioactivity

Much of this report deals with levels of radioactivity in various environmental media. The basic unit of radioactivity used in this report is the curie (Ci) (Table 1-2). The curie describes the amount of radioactivity present, and amounts are usually expressed in terms of fractions of curies in a given mass or volume (e.g., picocuries per liter). The curie is historically defined as the rate of nuclear disintegrations that occur in 1 gram of the radionuclide radium-226, which is 37 billion nuclear disintegrations per second. For any other radionuclide, 1 Ci is the quantity of the radionuclide that decays at this same rate. Nuclear disintegrations produce spontaneous emissions of alpha or beta particles, gamma radiation, or combinations of these.

1.8.4 Radiological Dose Units

The amount of ionizing radiation energy absorbed by a living organism is expressed in terms of radiological dose. Radiological dose in this report is usually written in terms of effective dose equivalent and reported numerically in units of millirem (mrem) (Table 1-3). Millirem is a term that relates ionizing radiation to biological effect or risk to humans. A dose of 1 mrem has a biological effect similar to the dose received from an approximate 1-day exposure to natural background radiation. An acute (short-term) dose of 100,000 to 400,000 mrem can cause radiation sickness in humans. An acute dose of 400,000 to 500,000 mrem, if left untreated, results in death approximately 50% of the time. Exposure to lower amounts of radiation (1,000 mrem or less) produces no immediate observable effects, but long-term (delayed) effects are possible. The average person in the United States receives an annual dose of approximately 300 mrem from exposure to naturally produced radiation. Medical and dental X-rays, air travel, and tobacco smoking add to this total.

The unit “rad,” for radiation absorbed dose, is also used in this report. The rad is a measure of the energy absorbed by any material, whereas a “rem,” for roentgen equivalent man, relates to both the amount of radiation energy absorbed by humans and its consequence. A roentgen (R) is a measure of radiation exposure. Generally speaking, 1 R of exposure will result in an effective dose equivalent of 1 rem. Additional information on radiation and dose terminology can be found in the Glossary (Appendix B).

1.8.5 International System of Units for Radioactivity and Dose

In some instances in this report, radioactivity and radiological dose values are expressed in other units in addition to Ci and rem. These units are the becquerel (Bq) and the sievert (Sv), respectively. The Bq and Sv belong to the International System of Units (SI), and their inclusion in this report is mandated by DOE. SI units are the internationally accepted units and may eventually be the standard for reporting both radioactivity and radiation dose in the United States. One Bq is equivalent to one nuclear disintegration per second.

The unit of radiation absorbed dose (rad) has a corresponding SI unit called the gray (Gy). The roentgen measure of radiation exposure has no SI equivalent. Table 1-4 provides the multiplication factors for converting to and from SI units.

Table 1-2. Units of radioactivity

Symbol	Name
Ci	curie
cpm	counts per minute
mCi	millicurie (1×10^{-3} Ci)
μ Ci	microcurie (1×10^{-6} Ci)
nCi	nanocurie (1×10^{-9} Ci)
pCi	picocurie (1×10^{-12} Ci)

Table 1-3. Units of radiological dose

Symbol	Name
mrad	millirad (1×10^{-3} rad)
mrem	millirem (1×10^{-3} rem)
R	roentgen
mR	milliroentgen (1×10^{-3} R)
μ R	microroentgen (1×10^{-6} R)

Table 1-4. Conversion table for SI units

To Convert From	To	Multiply By
becquerel (Bq)	picocurie (pCi)	27
curie (Ci)	becquerel (Bq)	3.7×10^{10}
gray (Gy)	rad	100
millirem (mrem)	millisievert (mSv)	0.01
millisievert (mSv)	millirem (mrem)	100
picocurie (pCi)	becquerel (Bq)	0.03704
rad	gray (Gy)	0.01
sievert (Sv)	rem	100

1.8.6 Radionuclide Nomenclature

Radionuclides are frequently expressed with the one- or two-letter chemical symbol for the element. Radionuclides may have many different isotopes, which are shown by a superscript to the left of the symbol. This number is the atomic weight of the isotope (the number of protons and neutrons in the nucleus of the atom).

Radionuclide symbols, many of which are used in this report, are shown in Table 1-5 along with the half-life of each radionuclide. The half-life is the time required for one-half of the radioactive atoms in a given amount of material to decay. For example, after one half-life, half of the original atoms will have decayed; after two half-lives, three-fourths of the original atoms will have decayed; and after three half-lives, seven-eighths of the original atoms will have decayed, and so on. The notation $^{236+238}\text{Ra}$ and similar notations in this report (e.g., $^{239+240}\text{Pu}$) are used when the analytical method does not distinguish between the isotopes, but reports the total amount of both.

1.8.7 Units of Measurement

Both metric and non-metric units of measurement are used in this report. Metric system and U.S. customary units and their respective equivalents are shown in Table 1-6 on the following page.

1.8.8 Measurement Variability

There is always uncertainty associated with the measurement of environmental contaminants. For radioactivity, a major source of uncertainty is the inherent randomness of radioactive decay events.

Uncertainty in analytical measurements is also the consequence of variability related to collecting and analyzing the samples. This variability is associated with reading or recording the result, handling or processing the sample, calibrating the counting instrument, and numerical rounding.

The uncertainty of a measurement is denoted by following the result with an uncertainty value, which is preceded by the plus-or-minus symbol, \pm . This uncertainty value gives information on what the measurement might be if the same sample were analyzed again under identical conditions. The uncertainty value implies that approximately 95% of the time, the average of many measurements would give a value somewhere between the reported value minus the uncertainty value and the reported value plus the uncertainty value. If the reported concentration of a given constituent is smaller than its associated uncertainty (e.g., 40 ± 200), then the sample may not contain that constituent.

Table 1-5. Radionuclides and their half-lives

Symbol	Radionuclide	Half-Life ^(a)
^{241}Am	americium-241	432.2 yr
^7Be	beryllium-7	53.44 d
^{14}C	carbon-14	5,730 yr
^{36}Cl	chlorine-36	3.01×10^5 yr
^{134}Cs	cesium-134	2.1 yr
^{137}Cs	cesium-137	30 yr
^{51}Cr	chromium-51	27.7 d
^{60}Co	cobalt-60	5.3 yr
^{152}Eu	europium-152	13.3 yr
^{154}Eu	europium-154	8.8 yr
^{155}Eu	europium-155	5 yr
^3H	tritium	12.35 yr
^{129}I	iodine-129	1.6×10^7 yr
^{131}I	iodine-131	8 d
^{40}K	potassium-40	1.3×10^8 yr
^{85}Kr	krypton-85	10^7 yr
^{212}Pb	lead-212	10.6 hr
^{238}Pu	plutonium-238	87.7 yr
^{239}Pu	plutonium-239	2.4×10^4 yr
^{240}Pu	plutonium-240	6.5×10^3 yr
^{241}Pu	plutonium-241	14.4 yr
^{226}Ra	radium-226	1.62×10^3 yr
^{228}Ra	radium-228	5.75 yr
^{220}Rn	radon-220	56 s
^{222}Rn	radon-222	3.8 d
^{103}Ru	ruthenium-103	39.3 d
^{106}Ru	ruthenium-106	368.2 d
^{125}Sb	antimony-125	2.8 yr
^{113}Sn	tin-113	115 d
^{90}Sr	strontium-90	29.1 yr
^{99}Tc	technetium-99	2.1×10^5 yr
^{232}Th	thorium-232	1.4×10^{10} yr
U ^(b)	uranium total	- - - ^(c)
^{234}U	uranium-234	2.4×10^5 yr
^{235}U	uranium-235	7×10^8 hr
^{238}U	uranium-238	4.5×10^9 yr
^{65}Zn	zinc-65	243.9 d
^{95}Zr	zirconium-95	63.98 d

(a) From Shleien (1992), except for ^{36}Cl (Browne et al. 1986)

(b) Total uranium may also be indicated by U-natural (U-nat) or U-mass

(c) Natural uranium is a mixture dominated by ^{238}U ; thus, the half-life is approximately 4.5×10^9 years

Table 1-6. Metric and U.S. customary unit equivalents

Metric Unit	U.S. Customary Equivalent Unit	U.S. Customary Unit	Metric Equivalent Unit
Length			
1 centimeter (cm)	0.39 inches (in.)	1 inch (in.)	2.54 centimeters (cm)
1 millimeter (mm)	0.039 inches (in.)		25.4 millimeters (mm)
1 meter (m)	3.28 feet (ft)	1 foot (ft)	0.3048 meters (m)
	1.09 yards (yd)	1 yard (yd)	0.9144 meters (m)
1 kilometer (km)	0.62 miles (mi)	1 mile (mi)	1.6093 kilometers (km)
Volume			
1 liter (L)	0.26 gallons (gal)	1 gallon (gal)	3.7853 liters (L)
1 cubic meter (m ³)	35.32 cubic feet (ft ³)	1 cubic foot (ft ³)	0.028 cubic meters (m ³)
	1.31 cubic yards (yd ³)	1 cubic yard (yd ³)	0.765 cubic meters (m ³)
Weight			
1 gram (g)	0.035 ounces (oz)	1 ounce (oz)	28.35 gram (g)
1 kilogram (kg)	2.21 pounds (lb)	1 pound (lb)	0.454 kilograms (kg)
1 metric ton (mton)	1.10 short ton (2,000 lb)	1 short ton (2,000 lb)	0.90718 metric ton (mton)
Area			
1 hectare	2.47 acres	1 acre	0.40 hectares
1 square meter (m ²)	10.76 square feet (ft ²)	1 square foot (ft ²)	0.09 square meters (m ²)
Radioactivity			
1 becquerel (Bq)	2.7×10^{-11} curie (Ci)	1 curie (Ci)	3.7×10^{10} becquerel (Bq)
Radiation dose			
1 rem	0.01 sievert (Sv)	1 sievert (Sv)	100 rem
Temperature			
$^{\circ}\text{C} = (^{\circ}\text{F} - 32)/1.8$		$^{\circ}\text{F} = (^{\circ}\text{C} \times 1.8) + 32$	

1.8.9 Mean and Standard Deviation

The mean of a set of data is the usual average of those data. The standard deviation (SD) of sample data relates to the variation around the mean of a set of individual sample results; it is defined as the square root of the average squared difference of individual data values from the mean. This variation includes both measurement variability and actual variation between monitoring periods (weeks, months, or quarters, depending on the particular analysis). The sample mean and standard deviation are estimates of the average and the variability that would be seen in a large number of repeated measurements. If the distribution shape were “normal” (i.e., shaped as \wedge), about 67% of the measurements would be within the mean \pm SD, and 95% would be within the mean \pm 2 SD.

1.8.10 Standard Error of the Mean

Just as individual values are accompanied by counting uncertainties, mean values (averages) are accompanied by uncertainty. The standard deviation of the distribution of sample mean values is known as the standard error of the mean (SE). The SE conveys how accurate an estimate the mean value is based on the samples that were collected and analyzed. The \pm value presented to the right of a mean value is equal to $2 \times \text{SE}$. The \pm value implies that approximately 95% of the time, the average of many calculated means will fall somewhere between the reported value minus the $2 \times \text{SE}$ value and the reported value plus the $2 \times \text{SE}$ value.

1.8.11 Median, Maximum, and Minimum Values

Median, maximum, and minimum values are reported in some sections of this report. A median value is the middle value when all the values are arranged in order of increasing or decreasing magnitude. For example, the median value in the series of numbers, 1 2 3 3 4 5 5 5 6, is 4. The maximum value would be 6 and the minimum value would be 1.

1.8.12 Less Than (<) Symbol

The “less than” symbol (<) is used to indicate that the measured value is smaller than the number given. For example, <0.09 would indicate that the measured value is less than 0.09. In this report, < is often used in reporting the amounts of nonradiological contaminants in a sample when the measured amounts are less than the analytical laboratory’s reporting limit for that contaminant in that sample. For example, if a measurement of benzene in sewage lagoon pond water is reported as <0.005 milligrams per liter, this implies that the measured amount of benzene present, if any, was not found to be above this level, given the sample and analysis methods used. For some constituents, the notation “ND” is also used to indicate that the constituent in question was not detected. For organic constituents, in particular, this could mean that the compound could not be clearly identified, the level (if any) was lower than the reporting limit, or (as often happens) both. The measurements of radionuclide concentrations are reported whether or not they are below the usual reporting limit (the minimum detectable concentration [see Glossary, Appendix B]).

1.8.13 Negative Radionuclide Concentrations

There is always a small amount of natural radiation in the environment. The instruments used in the laboratory to measure radioactivity in environmental media are sensitive enough to measure the natural, or background, radiation along with any contaminant radiation in a sample. To obtain an unbiased measure of the contaminant level in a sample, the natural, or background, radiation level must be subtracted from the total amount of radioactivity measured by an instrument. Because of the randomness of radioactive emissions and the very low concentrations of some contaminants, it is possible to obtain a background measurement that is larger than the actual contaminant measurement. When the larger background measurement is subtracted from the smaller contaminant measurement, a negative result is generated. The negative results are reported because they are useful when conducting statistical evaluations of the data.

Desert Research Institute

Environmental regulations pertinent to operations on the Nevada National Security Site (NNSS), the North Las Vegas Facility (NLVF), and the Remote Sensing Laboratory–Nellis (RSL–Nellis) are listed in this chapter. They include federal and state laws, state and local permit requirements, executive orders (EOs), U.S. Department of Energy (DOE) orders, and state agreements. They dictate how the U.S. Department of Energy, National Nuclear Security Administration Nevada Field Office (NNSA/NFO) conducts operations on and off the NNSS to ensure the protection of the environment and the public. The regulations are grouped by topic, and each topical subsection contains a brief description of the applicable regulations, a summary of noncompliance incidents (if any), a listing of compliance reports generated during or for the reporting year, and a compliance status table. Each table lists those measures or actions that are tracked or performed to ensure compliance with a regulation. A description of the field monitoring efforts, actions, and results that support the compliance status is found in subsequent chapters of this document, as noted in the “Reference Section” column of each table. At the end of this chapter, Table 2-13 presents the list of all environmental permits issued for the NNSS and the two Las Vegas area facilities.

2.1 Environmental Management and Sustainability

2.1.1 Applicable Regulations

EO 13423, *Strengthening Federal Environmental, Energy, and Transportation Management* – This EO requires federal facilities to establish goals to improve efficiency in energy and water use, procure goods and services that use sustainable environmental practices, reduce amounts of toxic materials acquired and maintain a cost-effective waste prevention and recycling program, ensure construction and major renovation of buildings that incorporate sustainable practices, reduce use of petroleum products in motor vehicles and increase use of alternative fuels, and acquire and dispose of electronic products using environmentally sound practices. These goals are to be incorporated into the Environmental Management System (EMS) of each federal facility. NNSA/NFO complies with this EO through adherence to DOE Order DOE O 436.1, “Departmental Sustainability.”

EO 13514, *Federal Leadership in Environmental, Energy, and Economic Performance* – This EO expands upon the energy reduction and environmental performance requirements of EO 13423. It requires all federal agencies to establish an integrated sustainability plan towards reducing greenhouse gas (GHG) emissions; conserving and protecting water resources through efficiency, reuse, and stormwater management (see Section 2.3); promoting pollution prevention and eliminating waste; constructing high performance sustainable buildings; purchasing energy efficient and environmentally preferred products; and reducing the use of fossil fuels through improved fleet management. DOE’s goals pertaining to EO 13514 were first published in the 2010 Strategic Sustainability Performance Plan (SSPP) (DOE 2010), which is updated each year (DOE 2014a). Site-specific goals for the NNSS that support DOE’s SSPP and compliance with this EO are incorporated into NNSA/NFO’s EMS and reported in a fiscal year NNSA/NFO Site Sustainability Plan (SSP) (National Security Technologies, LLC [NSTec], 2014a).

EO 13653, *Preparing the United States for the Impacts of Climate Change* – This EO outlines federal agency responsibilities in supporting climate resilient investment; managing lands and waters for climate preparedness and resilience; providing information, data, and tools for climate change preparedness and resilience; and planning. The *DOE Climate Change Adaptation Plan* (DOE 2014b) describes actions to be taken and lists specific goals and objectives that have been added to DOE’s SSPP. NNSA/NFO’s activities supporting DOE’s goals are reported in the annual NNSA/NFO fiscal year SSP (NSTec 2014a).

DOE O 436.1, Departmental Sustainability – This order incorporates and implements the requirements of EO 13514 and EO 13423 and requires each DOE site to set goals to achieve the DOE SSPP goals, use their EMS as the platform for establishing site-specific sustainability programs with objectives and measurable targets, develop and implement SSPs, and use alternative financing to the maximum extent possible for sustainability projects. NNSA/NFO reports adherence to this order and status towards reaching DOE SSPP goals in the annual NNSA/NFO fiscal year SSP (NSTec, 2014a).

Resource Conservation and Recovery Act (RCRA) – Under RCRA, hazardous waste (HW) generators are required to have a program in place to reduce the amount and toxicity of HW. Also, the U.S. Environmental Protection Agency (EPA) developed a list of types of commercially available products and specified that a certain minimum percentage of the product type’s content be composed of recycled materials if they are to be purchased by a federal agency. Federal facilities must have a procurement process in place to ensure that they purchase product types that satisfy the EPA-designated minimum percentages of recycled material.

Nevada Division of Environmental Protection (NDEP) Hazardous Waste Permit NEV HW0101 – This state permit requires NNSA/NFO to generate an annual summary report to include a description of efforts taken to reduce the volume and toxicity of waste generated in accordance with RCRA, as well as a description of the changes in volume and toxicity of waste achieved during the year in comparison to previous years.

2.1.2 Compliance Reports

The following reports were generated in 2014 for NNSA/NFO operations on the NNSS and at the two offsite facilities in compliance with regulations related to environmental protection; renewable energy and transportation management; environmental, energy, and economic performance; and pollution prevention and waste minimization:

- *FY 2015 NNSA/NFO Site Sustainability Plan* (NSTec 2014a)
- *RCRA Permit for a Hazardous Waste Management Facility Permit Number NEV HW0101- Annual Summary/Waste Minimization Report Calendar Year 2014, Nevada National Security Site, Nevada*, submitted to NDEP (NSTec 2015a)
- *FY 2014-0 EMS Annual Report*, submitted to DOE Headquarters (HQ) via entry into DOE HQ database

Table 2-1. NNSS compliance status with environmental management and sustainability regulations

Requirement	2014 Compliance Status	Section Reference ^(a)
DOE O 436.1, EO 13423, EO 13514, and EO 13653		
Annually update and implement an SSP to meet sustainability targets and goals.	Compliant	3.3.1; Table 3-1
Implement a validated EMS, which is certified to or conforming to International Organization for Standardization (ISO) 14001:2004.	Compliant	3.6
Include objectives and targets in the EMS that contribute to achieving the DOE Sustainable Environmental Stewardship goals.	Compliant	3.3
Monitor EMS progress and make such information available annually through the EMS Compliance Reporting using the Fed Center DOE HQ database.	Compliant	3.3; Table 3-1; 3.7
Resource Conservation and Recovery Act (RCRA)		
Have a program to reduce volume/quantity and toxicity of generated HW to the degree it is economically practicable.	Compliant	3.3.2
Have a process to ensure that EPA-designated list products are purchased containing the minimum content of recycled materials.	Compliant	3.3.2
NDEP Hazardous Waste Permit NEV HW0101		
Submit a calendar year Annual Summary/Waste Minimization Report to NDEP due March 1.	Compliant	3.3.2.1

(a) The section(s) within this document that describe how compliance summary data were collected

2.2 *Air Quality and Protection*

2.2.1 *Applicable Regulations*

Clean Air Act (CAA), National Emission Standards for Hazardous Air Pollutants (NESHAP) – Title III of the CAA establishes NESHAP to control those pollutants that might reasonably be anticipated to result in either an increase in mortality or an increase in serious irreversible or incapacitating but reversible illness. Industry-wide national emissions standards have been developed for 22 of 187 designated hazardous air pollutants (HAPs). Radionuclides and asbestos are among the 22 HAPs for which standards are established. NNSA/NFO NESHAP compliance activities include radionuclide air monitoring; reporting/notification of asbestos abatement; monitoring/reporting of emissions from generators, boilers, and management of gasoline and diesel storage tanks. At the NNS, NESHAP requirements are mainly met through adherence to State of Nevada Class II Air Quality Operating Permit (AP9711-2557); all approvals, notifications, requests for additional information, and reports required under the CAA are submitted to the State, Clark County, and the EPA Region IX in accordance with federal requirements. At NLVF and RSL-Nellis, NESHAP requirements are met through adherence to a Clark County Minor Source Permit and a Clark County Synthetic Minor Source Permit, respectively.

CAA, National Ambient Air Quality Standards (NAAQS) – Title I of the CAA establishes the NAAQS to limit levels of pollutants in the air for six “criteria” pollutants: sulfur dioxide, nitrogen oxides, carbon monoxide, ozone, lead, and particulate matter. Title V of the CAA authorizes states to implement permit programs to regulate emissions of these pollutants. For the NNS, there is one state-issued Class II Air Quality Operating Permit. The permit’s emission limits (except ozone and lead) are based on published emission values for other similar industries and on operational data specific to the NNS. Emissions from NNS operations are calculated and submitted to the State each year. Lead emissions are reported to the State as part of the total HAPs emissions. The NNS air permit also specifies visible emissions (opacity) limits for equipment/facilities as well as requirements for recordkeeping, performance testing, opacity field monitoring, particulate monitoring, and monitoring personnel certification. NLVF and RSL-Nellis operate under air quality permits that require semi-annual and annual reporting of hours of operation, emission quantities of criteria pollutants and HAPs, opacity for all operating equipment, certification of personnel who monitor opacity, and summaries of significant malfunctions and repairs.

CAA, New Source Performance Standards (NSPS) – Title I of the CAA establishes the NSPS to set minimum nationwide emission limitations for air pollutants from various industrial categories of facilities. NSPS pollutants include the six criteria pollutants plus other pollutants known as “designated pollutants.” A designated pollutant is any pollutant regulated by NSPS that is not a criteria pollutant. Examples of these are acid mist, fluorides, hydrogen sulfide in acid gas, and total reduced sulfur. The NSPS impose more stringent standards, including a reduced allowance of visible emissions (opacity), than under NAAQS. On the NNS, some screens, conveyor belts, bulk fuel storage tanks, and generators are subject to the NSPS, which Nevada regulates through the Class II Air Quality Operating Permit. One diesel generator located at the NLVF is also regulated by the NSPS.

CAA, Stratospheric Ozone Protection – Title VI of the CAA establishes production limits and a schedule for the phase-out of ozone-depleting substances (ODS). The EPA has established regulations for ODS recycling during servicing and disposal of air conditioning and refrigeration equipment, for repairing leaks in such equipment, and for safe ODS disposal. While there are no reporting requirements, recordkeeping to document the usage of ODS and technician certification is required, and the EPA may conduct random inspections to determine compliance. At the NNS, ODS are mainly used in air conditioning units in vehicles, buildings, refrigerators, drinking water fountains, vending machines, and laboratory equipment.

Nevada Administrative Code NAC 445B, Air Controls – In addition to enforcing the CAA regulations mentioned above, NAC 445B.22037 requires fugitive dust to be controlled. At the NNS, the Class II Air Quality Operating Permit includes a provision for site-wide surface disturbances and therefore requires implementation of an ongoing dust control program using the best practicable methods. Off the NNS, and excluding Clark County, all NNSA/NFO surface-disturbing activities that cover 5 or more acres are regulated by stand-alone Class II Surface Area Disturbance (SAD) permits issued by the State. NAC 445B.22067 prohibits the open burning of

combustible refuse and other materials unless specifically exempted by an authorized variance. At the NNSS, Open Burn Authorizations are routinely obtained for various fire training and emergency management exercises.

Other Air Quality Requirements – Title V Part 70 of the CAA requires owners or operators of air emission sources to pay annual state fees. Fees are based on a source’s “potential to emit,” and NNSS operations are subject to these fees. In addition, NNSA/NFO must allow Nevada’s Bureau of Air Pollution Control to conduct inspections of permitted NNSS facilities and allow the Clark County Department of Air Quality (DAQ) to conduct inspections of NLVF and RSL-Nellis permitted equipment.

2.2.2 Compliance Reports

The following reports were generated for 2014 NNSS operations in compliance with air quality regulations:

- *National Emission Standards for Hazardous Air Pollutants – Radionuclide Emissions, Calendar Year 2013*, submitted to EPA Region IX (NSTec 2015b)
- *Annual Asbestos Abatement Notification Form*, submitted to NDEP and to EPA Region IX
- *Calendar Year 2014 Actual Production/Emissions Reporting Form*, submitted to NDEP
- Quarterly Class II Air Quality Reports, submitted to NDEP
- Nonproliferation Test and Evaluation Complex (NPTEC) Pre-test and Post-test Reports, submitted to NDEP

The following reports were generated for 2014 operations at offsite facilities in compliance with air quality regulations:

- *Department of Air Quality Annual Emission Inventory Reporting Form for North Las Vegas Facility*, submitted to Clark County DAQ
- *Department of Air Quality Semi-Annual Report for Remote Sensing Laboratory*, submitted to Clark County DAQ
- *Department of Air Quality Annual Emission Inventory Reporting Forms for Remote Sensing Laboratory*, submitted to Clark County DAQ

Table 2-2. NNSS compliance status with applicable air quality regulations

Requirement	Compliance Limit	2014 Compliance Status	Section Reference ^(a)
Clean Air Act – NESHAP			
Estimate annual dose equivalent from all radioactive air emissions	10 millirem per year	Compliant	9.1.1.1
Submit notification of compliance for small area source boilers subject to tune-ups to NDEP	Due July 19, biennially	Compliant	--
Notify EPA Region IX if the number of linear feet (ft) or square feet (ft ²) of asbestos to be removed from a facility exceeds limit	260 linear ft or 160 ft ²	Compliant	4.2.8
Maintain asbestos abatement plans, data records, activity/ maintenance records	For up to 75 years	Compliant	4.2.8
Clean Air Act – NAAQS			
Submit annual and quarterly reports of calculated emissions at the NNSS to the State	Due March 1 and 30 days after end of each quarter, respectively	Compliant	4.2.3
Submit annual report of calculated emissions at NLVF and RSL-Nellis to Clark County	Due March 31	Compliant	A.1.1; A.2.1
Track tons of emissions of each criteria pollutant produced by permitted equipment/facility at the NNSS, NLVF, and RSL-Nellis based on calculations and actual operating information	PTE ^(b) varies	Compliant	4.2.3; Table 4-12; A.1.1; A.2.1
Submit semi-annual report of operating hours and throughputs for permitted equipment used at RSL-Nellis to Clark County	Due January 31 and July 31	Compliant	A.2.1
Track number of gallons of fuel used, hours of operation, and rate of aggregate/concrete production by permitted equipment/facility at the NNSS and stay within permitted limits of these parameters.	Limit varies ^(c)	1 non-compliance for hours of operation of an emergency generator	2.10, Table 2-12
Conduct opacity readings when in use for selected permitted equipment/facility at the NNSS, NLVF, and RSL-Nellis	Quarterly for NNSS, weekly for NLVF, daily for RSL-Nellis	Compliant	4.2.5; A.1.1; A.2.1
Measure percent opacity of emissions from permitted equipment/facility at the NNSS, NLVF, and RSL-Nellis	20%	Compliant	4.2.5; A.1.1; A.2.1
Conduct particulate monitoring for chemical releases/detonations at permitted chemical release and detonation sites on the NNSS	Monitoring report due ≤ 30 days from end of each quarter	Compliant	4.2.6
Submit test plans/final analysis reports to the State for each chemical release test or test series and for each detonation at permitted chemical release/detonation sites on the NNSS	Test plans due ≥ 30 days prior to tests, final reports due ≤ 30 days from end of each quarter	Compliant	4.2.6
Track rate and quantity of chemicals released at permitted chemical release sites and of explosives detonated at permitted detonation sites on the NNSS	Pounds per hour and tons per year; limits vary by chemical	Compliant	4.2.6
Track tons of criteria pollutant emissions and hazardous air pollutants at permitted chemical release sites and detonation sites on the NNSS	PTE ^(b) varies	Compliant	4.2.3; Table 4-12
Clean Air Act – NSPS			
Conduct opacity readings from permitted equipment/facility	Quarterly	Compliant	4.2.5
Measure percent opacity of emissions from permitted equipment/facility	10%	Compliant	4.2.5
Clean Air Act – Stratospheric Ozone Protection			
Maintain ODS technician certification records, approvals for ODS-containing equipment recycling/recovery, and applicable equipment servicing records	NA ^(d)	Compliant	4.2.7
Other Nevada Air Quality Permit Regulations			
Control fugitive dust for land-disturbing activities	NA	Compliant	4.2.9

(a) The section(s) within this document that describe how compliance summary data were collected

(b) Potential to emit = quantities of criteria pollutants that each facility/piece of equipment would emit annually if it were operated for the maximum hours specified in the air permit

(c) Compliance limit is specific for each piece of permitted equipment/facility (d) Not applicable

2.3 *Water Quality and Protection*

2.3.1 *Applicable Regulations*

Clean Water Act (CWA) – The CWA sets national water quality standards for contaminants in surface waters. It prohibits the discharge of contaminants from point sources to waters of the United States without a National Pollutant Discharge Elimination System (NPDES) permit. At the NNSS, CWA regulations are followed through compliance with permits issued by NDEP for wastewater discharges. Because there are no wastewater discharges to surface waters on or off site, there are no NPDES permits for the NNSS. At the NLVF, an NPDES permit regulates the discharge of pumped groundwater (see Appendix A, Section A.1.2.2). NPDES compliance is summarized in a format requested by DOE in Table 2-3 below. The EPA also requires the NLVF and RSL-Nellis to maintain and implement a Spill Prevention, Control, and Countermeasure (SPCC) Plan to ensure that petroleum and non-petroleum oil products do not pollute waters of the United States via discharge into the Las Vegas Wash.

Safe Drinking Water Act (SDWA) – The SDWA protects the quality of drinking water in the United States and authorizes the EPA to establish safe standards of purity. It requires all owners or operators of public water systems (PWSs) (see Glossary, Appendix B) to comply with National Primary Drinking Water Standards (health standards). State governments are authorized to set Secondary Standards related to taste, odor, and visual aspects. NAC 445A, “Water Controls,” requires that PWSs meet both primary and secondary water quality standards. The SDWA standards for radionuclides currently apply only to PWSs designated as community water systems, and the PWSs on the NNSS are permitted by the State as noncommunity water systems (see Glossary, Appendix B). Although not required under the SDWA, all potable water supply wells are monitored on the NNSS for radionuclides in compliance with DOE O 458.1, “Radiation Protection of the Public and the Environment” (see Section 2.4).

Energy Independence and Security Act of 2007 (EISA) – Section 438 of the EISA addresses storm water management and requires that any development or redevelopment project involving a federal facility with a footprint that exceeds 5,000 gross square feet (gsf) to use site planning, design, construction, and maintenance strategies for the property to maintain or restore, to the maximum extent technically feasible, the predevelopment hydrology of the property with regard to the temperature, rate, volume, and duration of storm water flow. In addition, EO 13514 (see Section 2.1) sets a policy that federal agencies conserve and protect water resources through proper storm water management. NNSA/NFO will meet this requirement for new development projects. No new construction projects of buildings greater than 5,000 gsf have been identified for 2015.

NAC 445A, Water Controls (Public Water Systems) – This NAC enforces the SDWA requirements and sets standards for permitting, design, construction, operation, maintenance, certification of operators, and water quality of PWSs. The NNSS has three PWSs and two potable water hauler trucks, which NDEP regulates through the issuance of permits.

NACs 444, Sanitation (Sewage Disposal) and 445A, Water Controls (Water Pollution Control) – These NACs regulate the collection, treatment, and disposal of wastewater and sewage at the NNSS. The requirements of these state regulations are issued in permits to NNSA/NFO for the E Tunnel Waste Water Disposal System, active and inactive sewage lagoons, septic tanks, septic tank pumpers, and a septic tank pumping contractor’s license. NNSA/NFO also obtains underground injection control (UIC) permits from NDEP, as required under NAC 445A.810–925, for various investigations. In 2012, a UIC permit was obtained for a noble gas migration study at borehole U20az PS#1A in Area 20. The permit was still active in 2014.

NAC 534, Underground Water and Wells – This NAC regulates the drilling, construction, and licensing of new wells and the reworking of existing wells to prevent the waste and contamination of underground waters. NNSA/NFO complies with this NAC as a matter of comity, holding to the position that state licensing requirements do not apply to the federal government and its contractors as a matter of law under the principle of federal supremacy and associated case law. The Underground Test Area (UGTA) activity, which drills new wells and reworks old wells, is the only NNSA/NFO operation that complies with this NAC.

UGTA Fluid Management Plan – UGTA wells are regulated by the State through an agreement between NNSA/NFO and NDEP called the UGTA Fluid Management Plan. The plan is followed in lieu of following separate state-issued water pollution control permits for each UGTA characterization well. Such permits ensure compliance with the CWA. The plan prescribes the methods of disposing groundwater pumped from UGTA wells during drilling, development, and testing based on the levels of radiological contamination. This plan is Attachment I of the UGTA Waste Management Plan (U.S. Department of Energy, National Nuclear Security Administration Nevada Site Office [NNSA/NSO] 2009).

2.3.2 Compliance Reports

The following reports were generated for NNS operations in 2014 in compliance with water quality regulations:

- *Quarterly Monitoring Reports for Nevada National Security Site Sewage Lagoons*, submitted to NDEP
- Results of water quality analyses for PWSs, sent to the State throughout the year as they were obtained from the analytical laboratory
- *Water Pollution Control Permit NEV 96021, Quarterly Monitoring Report* (for first, second, and third quarters of 2014 for E Tunnel effluent monitoring), submitted to NDEP
- *Water Pollution Control Permit NEV 96021, Quarterly Monitoring Report and Annual Summary Report for E Tunnel Wastewater Disposal System* (NSTec 2015c), submitted to NDEP

Beginning in 2014, annual and quarterly water quality reports were no longer required under North Las Vegas and Clark County water quality permits for the NLVF and RSL-Nellis (see Appendix A, Sections A.1.2.1 and A.2.2).

Table 2-3. Summary of NPDES permit compliance at NLVF in 2014

Permit Type	Outfall	Parameter ^(a)	Number of Permit Exceedances	Number of Samples Taken	Number of Compliant Samples	Percent Compliance	Date(s) Exceeded	Description/Solution
NV0023507	001 and 002	Daily maximum flow	0	365 (continuous)	365	100	NA ^(b)	NA
		TPH	0	1 (1/year)	1	100	NA	NA
		TSS	0	4 (1/quarter)	4	100	NA	NA
		TDS	0	4 (1/quarter)	4	100	NA	NA
		N	0	4 (1/quarter)	4	100	NA	NA
		pH	0	4 (1/quarter)	4	100	NA	NA
		Tritium	MR ^(c)	1 (1/year)	1	100	NA	NA

(a) TPH = total petroleum hydrocarbons, TSS = total suspended solids, TDS = total dissolved solids, N = total inorganic nitrogen

(b) NA = not applicable

(c) MR = monitor and report, no specified daily maximum or 30-day average limit, just the requirement that there shall be no discharge of substances that would cause a violation of state water quality standards

Table 2-4. NNSS compliance status with applicable water quality and protection regulations

Requirement	Compliance Limit	2014 Compliance Status	Section Reference ^(a)
Safe Drinking Water Act and NAC 445A, Water Controls (Public Water Systems)			
Monitor number of water samples containing coliform bacteria	1 per month per PWS	Compliant	5.2.1.1; Table 5-7
Measure concentration of inorganic and organic chemical contaminants and disinfection byproducts in permitted NNSS PWSs	Limit varies ^(b)	Aluminum and iron were above permit limits for Area 25 PWS	5.2.1.1; Table 5-7
Allow NDEP access to conduct inspections of PWS and water hauling trucks	NA ^(c)	Compliant	5.2.1.2
Clean Water Act - NPDES/State Pollutant Discharge Elimination System Permits and SPCC Plan			
Monitor water chemistry parameters quarterly and annually and monitor over 100 contaminants biennially in pumped groundwater at the NLVF	Limit varies	Compliant	A.1.2.2; Table A-2
Maintain and implement the SPCC Plan for the NLVF	NA	Compliant	A.1.2.5
Clean Water Act and NAC 444, Sanitation (Sewage Disposal)			
Adhere to all design/construction/operation requirements for new systems and those specified in septic system permits, septic tank pump truck permits, and septic tank pumping contractor permit	NA	Compliant	5.2.2
Clean Water Act and NAC 445A, Water Controls (Water Pollution Control)			
Monitor quarterly the 5-day biological oxygen demand (BOD ₅), total suspended solids (TSS), and pH in sewage lagoons	BOD ₅ : varies TSS: no limit pH: 6.0–9.0 S.U.	Compliant	5.2.3.1; Table 5-8
Monitor for 29 contaminants in permitted sewage lagoons only if specific or accidental discharges of potential contaminants occur	Limit varies	Compliant	5.2.3.1
Submit quarterly monitoring reports for two active sewage lagoons (for Areas 6 and 23)	Due end of April, July, October, January	Compliant	5.2.3.1
Inspection by operator of active and inactive sewage lagoon systems	Weekly and quarterly	Compliant	5.2.3.2
Monitor quarterly concentrations of tritium (³ H), gross alpha (α), gross beta (β) (in picocuries per liter [pCi/L]); and 14 nonradiological contaminants/water parameters; and monitor monthly the flow rate, pH, and specific conductance (SC) from E Tunnel discharge water samples	³ H: 1,000,000 pCi/L α : 35 pCi/L β : 100 pCi/L Non-rad: Limit varies	Compliant	5.1.3.7.2; Table 5-4; 5.2.4; Table 5-9
Monitor every 24 months the concentrations of ³ H, α , β , and 16 nonradiological contaminants/water quality parameters in Well ER-12-1 water samples	³ H: 20,000 pCi/L α : 15 pCi/L; β : 50 pCi/L Non-rad: Limit varies	Compliant	5.1.3.7.2; Table 5-4; 5.2.4; Table 5-9
Annually submit a Zero Discharge Form for the RSL-Nellis sewage outfall	Limit varies	Compliant	A.2.2
Adhere to NDEP UIC permit requirements for noble gas migration study in Area 20	NA	Compliant	—
NAC 534, Underground Water and Wells, and UGTA Fluid Management Plan			
Maintain State well-drilling license for personnel supervising well construction/reconditioning	NA	Compliant	—
For UGTA well drilling fluids, monitor tritium and lead levels (in milligrams per liter [mg/L]), manage fluids, notify NDEP as required based on decision criteria limits	³ H >200,000 pCi/L, Lead >5 mg/L	Compliant	5.1.3.7.3
Adhere to well construction requirements/waivers, maintain records, submit required reports	NA	Compliant	—

(a) The section(s) within this document that describe how compliance summary data were collected

(b) Compliance limit is specific for each contaminant; see referenced tables for specific limits

(c) NA = Not applicable

2.4 Radiation Protection

2.4.1 Applicable Regulations

Clean Air Act (CAA), National Emission Standards for Hazardous Air Pollutants (NESHAP) – NESHAP (Title 40 Code of Federal Regulations [CFR] Part 61 Subpart H) establishes a radiation dose limit of 10 millirem per year (mrem/yr) (0.1 millisievert per year [mSv/yr]) to individuals in the general public from the air pathway. NESHAP also specifies “Concentration Levels for Environmental Compliance” (abbreviated as compliance levels [CLs]) for radionuclides in air. A CL is the annual average concentration of a radionuclide that could deliver a dose of 10 mrem/yr (0.1 mSv/yr). The CLs are provided for facilities, such as the NNSS, which use air sampling at offsite receptor locations to demonstrate compliance with the NESHAP public radiation dose limit. Sources of NNSS radioactive air emissions include containment ponds, Area 5 Radioactive Waste Management Complex (RWMC), Sedan and Schooner craters, calibration of analytical equipment, and contaminated soil at nuclear device safety test and atmospheric test locations.

Safe Drinking Water Act (SDWA) – The National Primary Drinking Water Regulations (40 CFR 141) promulgated by the SDWA require that the maximum contaminant level goal for any radionuclide be zero. But, when this is not possible (e.g., in groundwater containing naturally occurring radionuclides), the SDWA specifies that the concentration of one or more radionuclides should not result in a whole body or organ dose greater than 4 mrem/yr (0.04 mSv/yr). Sources of radionuclide contamination in groundwater at the NNSS are the underground nuclear tests detonated near or below the water table (see Glossary, Appendix B).

DOE O 458.1, Radiation Protection of the Public and the Environment – DOE O 458.1 requires DOE sites to establish and document an environmental radiological protection program. The order establishes requirements for (1) measuring radioactivity in the environment, (2) documenting the ALARA [as low as reasonably achievable] process for operations, (3) using mathematical models for estimating radiation doses, (4) releasing property having residual radioactive material, and (5) maintaining records to demonstrate compliance. DOE O 458.1 sets a radiation dose limit of 100 mrem/yr (1 mSv/yr) above background levels to individuals in the general public from all pathways of exposure combined. The order calls for the protection of populations of terrestrial plants and aquatic and terrestrial animals from radiological impacts through the use of DOE Standard DOE-STD-1153-2002, “A Graded Approach for Evaluating Radiation Doses to Aquatic and Terrestrial Biota.”

DOE-STD-1196-2011, Derived Concentration Technical Standard – This standard, issued in April 2011, defines the Derived Concentration Standards (DCSs) (see Glossary, Appendix B) used in the design and conduct of radiological environmental protection programs at DOE facilities and sites. DCSs represent the concentration of a given radionuclide in either water or air that results in a member of the public receiving 100 mrem (1 mSv) effective dose following continuous exposure for 1 year via each of the following pathways: ingestion of water, submersion in air, and inhalation. They replace the Derived Concentration Guides (DCGs), which were previously published by DOE in 1993 in DOE O 5400.5, “Radiation Protection of the Public and the Environment.” Previous versions of this report used DCGs to evaluate environmental monitoring results. With the issuance of DOE O 458.1 and DOE-STD-1196-2011, this report will now report environmental monitoring results according to the corresponding DCSs.

DOE-STD-1153-2002, A Graded Approach for Evaluating Radiation Doses to Aquatic and Terrestrial Biota – This standard provides methods, computer models, and guidance in implementing a graded approach to evaluating the radiation doses to populations of aquatic animals, terrestrial plants, and terrestrial animals residing on DOE facilities. Dose limits of 1 rad per day (rad/d) (10 milligray per day [mGy/d]) for terrestrial plants and aquatic animals, and of 0.1 rad/d (1 mGy/d) for terrestrial animals are specified by this DOE standard. Dose rates below these levels are believed to cause no measurable adverse effects to populations of plants and animals.

DOE O 435.1, Radioactive Waste Management – This order requires that all DOE radioactive waste be managed in a manner that is protective of the worker, public health and safety, and the environment. It directs how radioactive waste management operations are conducted on the NNSS. The Area 3 Radioactive Waste

Management Site (RWMS) and the Area 5 RWMC operate as Category II Non-Reactor Nuclear Facilities. They are designed and operated to manage and safely dispose of low-level waste (LLW), mixed low-level waste (MLLW), and HW generated by NNSA/NFO, other DOE, or selected U.S. Department of Defense (DoD) operations and to manage and safely store transuranic (TRU) and mixed transuranic (MTRU) wastes generated on site for eventual shipment to the Waste Isolation Pilot Plant (WIPP) in Carlsbad, New Mexico. The manual for this order (DOE M 435.1-1) specifies that operations at NNSS radioactive waste management facilities must not contribute a dose to the general public in excess of 25 mrem/yr.

2.4.2 Compliance Reports

- *National Emission Standards for Hazardous Air Pollutants – Radionuclide Emissions, Calendar Year 2014*, submitted to EPA Region IX (NSTec 2015b)
- This document, the *Nevada National Security Site Environmental Report 2014*, was generated to report 2014 compliance with DOE O 458.1 and DOE-STD-1153-2002.

Table 2-5. NNSS compliance status with regulations for radiation protection of the public and the environment

Requirement	Compliance Limit	2014 Compliance Status	Section Reference ^(a)
Clean Air Act – NESHAP			
Estimate annual dose above background levels to the general public from radioactive air emissions	10 mrem/yr	Compliant	9.1.1.1
Safe Drinking Water Act			
Estimate annual dose to the general public from drinking water	4 mrem/yr	Compliant ^(b)	9.1.1.4
DOE O 458.1, Radiation Protection of the Public and the Environment			
Estimate annual dose above background level to the general public from all pathways	100 mrem/yr	Compliant	9.1.3
Determine total residual surface contamination of property released off site (in disintegrations per minute per 100 square centimeters [dpm/100 cm ²])	300–15,000 dpm/100 cm ² depending on the radionuclide	Compliant	9.1.5
DOE-STD-1153-2002, A Graded Approach for Evaluating Radiation Doses to Aquatic and Terrestrial Biota			
Estimate absorbed radiation dose to terrestrial plants and aquatic animals	1 rad/d	Compliant	9.2
Estimate absorbed radiation dose to terrestrial animals	0.1 rad/d	Compliant	9.2
DOE O 435.1, Radioactive Waste Management			
Estimate annual dose to the general public due to waste management operations	25 mrem/yr	Compliant	9.1.2

(a) The section(s) within this document that describe how compliance summary data were collected

(b) Migration of radioactivity in groundwater to offsite public or private drinking water wells has never been detected

2.5 *Waste Management and Environmental Restoration*

2.5.1 *Applicable Regulations*

Atomic Energy Act (AEA) of 1954 – The AEA ensures the proper management of source, special nuclear, and byproduct material. At the NNSS, AEA regulations are followed through compliance with DOE O 435.1 and 10 CFR 830, “Nuclear Safety Management.”

10 CFR 830, Nuclear Safety Management – This CFR establishes requirements for the safe management of work at DOE’s nuclear facilities. It governs the possession and use of special nuclear and byproduct materials. It also covers activities at facilities where no nuclear material is present, such as facilities that prepare the non-nuclear components of nuclear weapons, but that could cause radiological damage at a later time. It governs the conduct of the management and operating contractor and other persons at DOE nuclear facilities, including facility visitors. When coupled with the Price-Anderson Amendments Act (PAAA) of 1988, it provides DOE with authority to assess civil penalties for the violation of rules, regulations, or orders relating to nuclear safety by contractors, subcontractors, and suppliers who are indemnified under PAAA.

DOE O 435.1, Radioactive Waste Management – This order requires that all DOE radioactive waste be managed in a manner that is protective of the worker, public health and safety, and the environment. On the NNSS, the Area 3 RWMS and the Area 5 RWMC operate as Category II Non-Reactor Nuclear Facilities. They are designed and operated to manage and safely dispose of LLW, MLLW, and hazardous waste generated by NNSA/NFO, other DOE, or selected DoD operations and to manage and safely store TRU and MTRU wastes generated on site for eventual shipment to the WIPP in Carlsbad, New Mexico.

Resource Conservation and Recovery Act (RCRA) – 40 CFR 239–282 – RCRA is the nation’s primary law governing the management of solid waste and HW. RCRA regulates the storage, transportation, treatment, and disposal of such wastes to prevent contaminants from leaching into the environment from landfills, underground storage tanks (USTs), surface impoundments, and HW disposal facilities. The EPA authorizes the State of Nevada to administer and enforce RCRA regulations. RCRA also requires generators of HW to have a program in place to reduce the volume or quantity and toxicity of HW generated. Such NNSS programs are addressed in Sections 2.6 and 3.3.2 on Pollution Prevention and Waste Minimization.

Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA)/Superfund Amendments and Reauthorization Act (SARA) – These acts provide a framework for the cleanup of waste sites containing hazardous substances and an emergency response program in the event of a release of a hazardous substance to the environment. No HW cleanup operations on the NNSS are regulated under CERCLA; they are regulated under RCRA instead. The applicable requirements of CERCLA pertain to an emergency response program for hazardous substance releases (see Emergency Planning and Community Right-to-Know Act in Section 2.6) and to how state laws concerning the removal and remediation of hazardous substances apply to federal facilities (specifically, implementation of the Federal Facility Agreement and Consent Order).

Federal Facility Agreement and Consent Order (FFACO), as amended – Pursuant to Section 120(a)(4) of CERCLA and to Sections 6001 and 3004(u) of RCRA, this consent order, agreed to by the State of Nevada, DOE Environmental Management, the U.S. Department of Defense, and DOE Legacy Management became effective in May 1996. It addresses the environmental restoration of historically contaminated sites at the NNSS, parts of the Tonopah Test Range, parts of the Nevada Test and Training Range (NTTR), the Central Nevada Test Area, and the Project Shoal Area. Under the FFACO, hundreds of sites have been identified for cleanup and closure. An individual site is called a corrective action site (CAS). Multiple CASs are typically grouped into corrective action units (CAUs). NNSA/NFO is responsible for the CASs included in the UGTA, Soils, and Industrial Sites activities, while DOE Legacy Management is responsible for the CASs at the Central Nevada Test Area and the Project Shoal Area.

NAC 444.850–444.8746, Disposal of Hazardous Waste – This NAC regulates the operation of HW disposal facilities on the NNSS to comply with federal RCRA regulations. Through this NAC, RCRA Part B Permit NEV HW0101 regulates the operation of the Hazardous Waste Storage Unit (HWSU) in Area 5, the Explosive Ordnance Disposal Unit (EODU) in Area 11, the storage of onsite and offsite MLLW in designated Area 5 locations prior to treatment and/or disposal, and the disposal of MLLW received from DOE offsite facilities into Cell 18, the permitted Mixed Waste Disposal Unit. The state permit requires groundwater monitoring of three wells downgradient of the MLLW disposal cells, prescribes post-closure monitoring for HW sites that were closed under RCRA prior to enactment of the FFACO, and requires preparation of an EPA Hazardous Waste Report of all HW and MLLW volumes generated and disposed annually at NNSS and all HW generated annually at the NLVF.

NAC 444.570–444.7499, Solid Waste Disposal – This NAC sets standards for solid waste management systems, including the storage, collection, transportation, processing, recycling, and disposal of solid waste. The NNSS has one inactive and four active permitted landfills. Active units include the Area 5 Asbestiform Low-Level Solid Waste Disposal Unit (P06), Area 6 Hydrocarbon Disposal Site, Area 9 U10c Solid Waste Disposal Site, and Area 23 Solid Waste Disposal Site. These landfills are designed, constructed, operated, maintained, and monitored in adherence to the requirements of their state-issued permits. The Area 5 Asbestiform Low-Level Solid Waste Disposal Unit P07 is inactive.

NAC 459.9921–459.999, Storage Tanks – This NAC enforces the federal regulations under RCRA pertaining to the maintenance and operation of fuel tanks (including underground fuel storage tanks) so as to prevent environmental contamination. The NNSS has five USTs and RSL-Nellis has seven USTs. The tanks are either (1) fully regulated under RCRA and registered with the State, (2) regulated under RCRA and registered with the State but deferred from leak detection requirements, or (3) excluded from federal and state regulation. At RSL-Nellis, NDEP allows the Southern Nevada Health District to enforce this NAC with the issuance of county permits to NNSA/NFO.

2.5.2 Compliance Reports

The following reports were prepared and submitted to NDEP to comply with environmental regulations for waste management and environmental restoration operations conducted on the NNSS in 2014.

- *Nevada National Security Area 5 Solid Waste Disposal Annual Report for CY 2014*, January 2015
- NNSS Quarterly Volume Reports (for all active LLW and MLLW disposal cells), April, July, and October 2014, and January 2015
- *4th Quarter Transportation Report FY2014, Radioactive Waste Shipments to and from the Nevada National Security Site*, November 2014 (NSTec 2014b)
- *RCRA Permit for a Hazardous Waste Management Facility Permit Number NEV HW0101 – Annual Summary/Waste Minimization Report Calendar Year 2014*, February 2015 (NSTec 2015a)
- *Nevada National Security Site 2014 Data Report: Groundwater Monitoring Program Area 5 Radioactive Waste Management Site*, February 2015 (NSTec 2015d)
- *Nevada National Security Site 2014 Waste Management Monitoring Report - Area 3 and Area 5 Radioactive Waste Management Site* (NSTec 2015e)
- *Post-Closure Report for Closed Resource Conservation and Recovery Act Corrective Action Units, Nevada National Security Site, Nevada, for Fiscal Year 2014 (October 2013–September 2014)*, January 2015 (NNSA/NFO 2015a)
- *Post-Closure Inspection Letter Report for Corrective Action Units on the Nevada National Security Site*, May 2015 (NNSA/NFO 2015b)
- *Post-Closure Inspection Report for the Tonopah Test Range, Nevada, for Calendar Year 2014*, March 2015 (NNSA/NFO 2015c)
- *Annual Soil Moisture Monitoring Report for the Area 9 U10c Landfill, Nevada National Security Site, Nevada, for the Period March 2014 – February 2015*

- *January–June 2014 Biannual Solid Waste Disposal Site Report for the Nevada National Security Site Area 23 Sanitary Landfill, July 2014*
- *July–December 2014 Biannual Solid Waste Disposal Site Report for the Nevada National Security Site Area 23 Sanitary Landfill, January 2015*
- *Annual Soil Moisture Monitoring Report for the Area 6 Hydrocarbon Landfill, Nevada National Security Site, Nevada, for the Period March 2014–February 2015*

The following Environmental Restoration reports/presentations for CAUs were submitted to NDEP in 2014 in accordance with the FFACO schedule.

CAU 97: Yucca Flat/Climax Mine – Corrective Action Investigation Plan, Record of Technical Change 1

CAU 97: Yucca Flat/Climax Mine – Corrective Action Investigation Plan, Record of Technical Change 2

CAU 97: Yucca Flat/Climax Mine – Phase I Flow and Transport Model Document, Record of Technical Change 1

CAU 567: Miscellaneous Soil Sites – Corrective Action Decision Document/Closure Report

CAU 568: Area 3 Plutonium Dispersion Sites – Corrective Action Investigation Plan

CAU 571: Area 9 Yucca Flat Plutonium Dispersion Sites – Corrective Action Decision Document/Closure Report

CAU 573: Alpha Contaminated Sites – Corrective Action Investigation Plan

CAU 575: Area 15 Miscellaneous Sites – Streamlined Approach for Environmental Restoration Plan

Table 2-6. NNSS compliance status with applicable waste management and environmental restoration regulations

Requirement	Compliance Limit	2014 Compliance Status	Section Reference ^(a)
10 CFR 830, Nuclear Safety Management			
Complete and maintain proper conduct of operations documents required for Class II Nuclear Facility for disposal/characterization/storage of radioactive waste	6 types of guiding documents required	Compliant	10.1.6; Table 10-2
DOE O 435.1, Radioactive Waste Management			
Establish/maintain Waste Acceptance Criteria for radioactive wastes received at Area 3 and 5 RWMSs	NA ^(b)	Compliant	10.1.5
Track annual volume of LLW and MLLW disposed at Area 3 and Area 5 RWMSs (in cubic meters [m ³])	NA	Compliant	10.1.1; Table 10-1
Vadose zone monitoring at Area 3 and Area 5 RWMSs, not required by order, but performed to validate performance assessment criteria of RWMSs	NA	Conducted	10.1.8
Resource Conservation and Recovery Act (as enforced through permits issued by the State of Nevada)			
Monitor semi-annually the pH, specific conductance (SC), total organic carbon (TOC), total organic halides (TOX), and tritium (³ H) and 11 general water chemistry parameters in groundwater from Wells UE5 PW-1, UE5 PW-2, and UE5 PW-3 to verify performance of Cell 18, the new Area 5 MWDU ^(c)	pH: 7.6 to 9.2 SC: 0.440 mmhos/cm ^(d) TOC: 1 mg/L ^(e) ; TOX: 50 µg/L ^(f) H ³ : 2,000 pCi/L	Compliant	10.1.7; Table 10-3
Track the volume of MLLW disposed in Cell 18 (the Area 5 MWDU)	25,485 m ³ (899,994 ft ³)	Compliant	10.1.1; Table 10-1
Track the volume of nonradioactive HW stored at the HWSU	61,600 liters (16,280 gallons)	Compliant	10.2.1; Table 10-5
Track the weight of approved explosive ordnance wastes detonated at the EODU (in kilograms [kg] or pounds [lb])	45.4 kg (100 lb) at a time, not to exceed 1 detonation event/hour	Compliant	10.2.1; Table 10-5
Submit quarterly and annual reports to the State of Nevada for volumes in m ³ of HW wastes received at the Area 5 MWSU ^(g) , HWSU, EODU, and Cell 18	Due April, July, October, January; annual report due March 1	Compliant	10.2.1
Submit Annual Hazardous Waste Report for NNSS and NLVF to the State of Nevada	Due the following February	Compliant	10.2.1
Conduct vadose zone monitoring for RCRA closure site U-3ax/bl Subsidence Crater	Continuous monitoring using TDR ^(h) sensors	Compliant	10.1.8; 11.4; Table 11-4
Conduct periodic post-closure site inspections of five historic RCRA closure sites (CAUs 90, 91, 92, 110, 112)	NA	Compliant	11.4; Table 11-4
Upgrade, remove, and report on USTs at NNSS and RSL-Nellis	NA	Compliant	10.3
Federal Facility Agreement and Consent Order			
Adhere to calendar year work scope for site characterization, remediation, closures, and post-closure monitoring and inspection	18 CAUs identified for some phase of action in 2014	Compliant	11.1; 11.2; 11.3
NAC 444.750-8396, Solid Waste Disposal			
Track weight and volume of waste disposed each calendar year	Areas 6 and 9 – No limit Area 23 – 20 tons/day	Compliant	10.4; Table 10-6
Monitor vadose zone for the Area 6 Hydrocarbon and Area 9 U10c Solid Waste disposal sites	Annually using neutron logging through access tubes	Compliant	10.4

(g) MWSU = Mixed Waste Storage Unit

(h) Time domain reflectometry

2.6 *Hazardous Materials Control and Management*

2.6.1 *Applicable Regulations*

Toxic Substances Control Act (TSCA) – This act requires testing and regulation of chemical substances that enter the consumer market. Because the NNSS does not produce chemicals, compliance is primarily directed toward the management of polychlorinated biphenyls (PCBs). At the NNSS, remediation activities and maintenance of fluorescent lights can result in the onsite disposal of PCB-contaminated waste and light ballasts or the offsite disposal of larger quantities of such PCB waste at an approved PCB disposal facility. NNSS also receives radioactive waste for disposal that may contain regulated levels of PCBs. When received, the TSCA requires the NNSS disposal facility to issue a Certificate of Disposal for PCBs to the waste-generating facility. These certificates are issued under the NNSS Waste Management program (see Section 10.1.1). The onsite disposal of all PCB wastes and recordkeeping requirements for PCB activities are regulated on the NNSS by the State of Nevada.

Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA) – This act sets forth procedures and requirements for pesticide registration, labeling, classification, devices for use, and certification of applicators. The use of certain pesticides (called “restricted-use pesticides”) is regulated. The use of non-restricted–use pesticides (as available in consumer products) is not regulated. On the NNSS, both restricted-use and non-restricted–use pesticides are applied under the direction of a State of Nevada–certified applicator.

Emergency Planning and Community Right-to-Know Act (EPCRA) – This act is a provision of the 1986 SARA Title III amendments to CERCLA. It requires that federal, state, and local emergency planning authorities be provided information regarding the presence and storage of hazardous substances and their planned and unplanned environmental releases, including provisions and plans for responding to emergency situations involving hazardous materials. EO 13514 requires all federal facilities to report in accordance with the requirements of Sections 301 through 313 of EPCRA. NNSA/NFO is required to submit reports pursuant to Sections 302, 303, 304, 311, 312, and 313 of SARA Title III described below. Compliance with these EPCRA reporting requirements is summarized in Table 2-7.

- **Section 302–303, Planning Notification** – Requires the state emergency response commission and the local emergency planning committee to be notified when an extremely hazardous substance (EHS) is present at a facility in excess of the threshold planning quantity. An inventory of the location and amounts of all hazardous substances stored on the NNSS and at the two offsite facilities is maintained. Inventory data are included in an annual report called the Nevada Combined Agency (NCA) Report. Also, NNSA/NFO monitors hazardous materials while they are in transit on the NNSS through a hazardous materials notification system called HAZTRAK.
- **Section 304, Extremely Hazardous Substances Release Notification** – Requires the local emergency planning committee and state emergency response agencies to be notified immediately of accidental or unplanned releases of an EHS to the environment. Also, the national response center is notified if the release exceeds the CERCLA reportable quantity for the particular hazardous substance.
- **Section 311–312, Material Safety Data Sheet/Safety Data Sheet (MSDS/SDS)/Chemical Inventory** – Requires facilities to provide applicable emergency response agencies with MSDSs/SDSs, or a list of MSDSs/SDSs for each hazardous chemical stored on site. This is essentially a one-time reporting unless chemicals or products change. Any new MSDSs/SDSs are provided annually in the NCA Report. Section 312 requires facilities to report maximum amounts of chemicals on site at any one time. This report is submitted to the State Emergency Response Commission, the Local Emergency Planning Committee, and the local fire departments.
- **Section 313, Toxic Release Inventory (TRI) Reporting** – Requires facilities to submit an annual report titled “Toxic Chemical Release Inventory, Form R” to the EPA and to the State of Nevada if annual usage quantities of listed toxic chemicals exceed specified thresholds. Toxic chemical releases on the NNSS above threshold limits are reported to the EPA and the State Emergency Response Commission in the TRI, Form R report.

NAC 555, Control of Insects, Pests, and Noxious Weeds – This NAC provides the regulatory framework for certification of several classifications of registered pesticide and herbicide applicators in the state of Nevada. The Nevada Department of Agriculture (NDOA) administers this program and has the primary role to enforce FIFRA in Nevada. Inspections of pesticide/herbicide applicator programs are carried out by NDOA.

NAC 444, Sanitation – Polychlorinated Biphenyls (PCBs) – This code enforces the federal requirements for the handling, storage, and disposal of PCBs and contains recordkeeping requirements for PCB activities.

State of Nevada Chemical Catastrophe Prevention Act – This act directed NDEP to develop and implement a program called the Chemical Accident Prevention Program (CAPP). The act requires registration of facilities storing highly hazardous substances above listed thresholds. NNSA/NFO submits an annual CAPP registration report to NDEP.

2.6.2 Compliance Reports

The following reports were generated for 2014 NNSA/NFO operations on the NNSS and at the two offsite facilities in compliance with hazardous materials control and management regulations:

- *Nevada Combined Agency Hazmat Facility Report – Calendar Year (CY) 2014*, submitted to state and local agencies
- *Toxic Release Inventory Report, Form R for CY 2014*, submitted to the EPA and the State
- *Chemical Accident Prevention Program 2015 Registration*, submitted to NDEP

Table 2-7. Status of EPCRA reporting

EPCRA Section	Description of Reporting	2014 Status ^(a)
Section 302	Emergency Planning Notification	Yes
Section 304	EHS Release Notification	Not required
Section 311–312	MSDS/Chemical Inventory	Yes
Section 313	TRI Reporting	Yes

(a) “Yes” indicates that NNSA/NFO reported under the requirements of the EPCRA section specified (see Section 12.3, Table 12-1).

Table 2-8. NNSS compliance status with applicable regulations for hazardous substance control and management

Requirement	Compliance Limit	2014 Compliance Status	Section Reference ^(a)
Toxic Substances Control Act (TSCA) and NAC 444, Sanitation – Polychlorinated Biphenyls			
Store and dispose PCB materials off site	Required if >50 ppm ^(b) PCBs	Compliant	12. 1
Store and dispose PCB materials on site	Allowed if <50 ppm PCBs	No onsite storage or disposal	12. 1
Dispose on site bulk product waste containing PCBs generated by remediation and site operations	Case-by-case approval by NDEP	No bulk product wastes were generated for onsite disposal	12. 1
Issue a Certificate of Disposal for PCBs to the waste-generating facility bringing radioactive waste containing regulated levels of PCBs to the NNSS for disposal	Due within 30 days after receipt of waste	Compliant	10.1.1
Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA) and NAC 555, Control of Insects, Pests, and Noxious Weeds			
Use restricted-use pesticides under the direct supervision of an individual who is a state-certified applicator	NA ^(c)	Compliant	12. 2
Maintain state certification of onsite pesticide and herbicide applicator	NA	Compliant	12. 2
Emergency Planning and Community Right-to-Know Act (EPCRA)			
Adhere to reporting requirements	Varies by EPCRA section ^(d) Routine reports: NCA Report due March 1 for previous CY; TRI Report, Form R due July 1 for previous CY	Compliant	12. 3
State of Nevada Chemical Catastrophe Prevention Act			
Registration of NNSS with the State if highly hazardous substances are stored above listed threshold quantities	NDEP CAPP ^(e) Report due June 21 for previous period of June 1 through May 31	Compliant	12. 4

(a) The section(s) within this document that describe how compliance summary data were collected

(b) ppm = parts per million

(c) Not applicable

(d) Reporting criteria varies across EPCRA Sections (i.e., 302–304 and 311–313). See Table 2-7; Section 12.3, Table 12-1.

(e) CAPP = Chemical Accident Prevention Program

2.7 National Environmental Policy Act

DOE O 451.1B, “National Environmental Policy Act Program,” establishes DOE requirements and responsibilities for implementing the National Environmental Policy Act of 1969 (NEPA), the Council on Environmental Quality Regulations Implementing the Procedural Provisions of NEPA (40 CFR 1500–1508), and the DOE NEPA Implementing Procedures (10 CFR 1021). Under NEPA, federal agencies are required to consider environmental effects and values and reasonable alternatives before making a decision to implement any major federal action that may have a significant impact on the human environment. Before any project or activity is initiated at the NNS, it is evaluated for possible impacts to the environment. NNSA/NFO uses four levels of documentation to demonstrate compliance with NEPA:

- Environmental Impact Statement (EIS) – a full disclosure of the potential environmental effects of proposed actions and the reasonable alternatives to those actions. An EIS must be prepared by a federal agency when a “major” federal action that will have “significant” environmental impacts is planned. For large multi-program or multiple facility sites, a programmatic EIS is prepared.
- Environmental Assessment (EA) – a concise discussion of proposed actions and alternatives and the potential environmental effects to determine if an EIS is necessary
- Supplement Analysis (SA) – a collection and analysis of information for an action already addressed in an existing EIS or EA used to determine whether a supplemental EIS or EA should be prepared, a new EIS or EA should be prepared, or no further NEPA documentation is required
- Categorical Exclusion (CX) – a category of actions that do not have a significant adverse environmental impact based on similar previous activities and for which, therefore, neither an EA nor an EIS is required

A NEPA Environmental Evaluation Checklist (Checklist) is required for all proposed projects or activities on the NNS. The Checklist is reviewed by the NNSA/NFO NEPA Compliance Officer to determine if the activity’s environmental impacts have been addressed in existing NEPA documents. If a proposed project has not been covered under any previous NEPA analysis and it does not qualify as a CX, a determination is made to initiate the appropriate level of NEPA analysis and documentation. The analysis may result in preparation of a new EA, EIS, or supplemental document to the existing programmatic NNS EIS (U.S. Department of Energy, Nevada Operations Office [DOE/NV] 1996). The NEPA Compliance Officer must approve each Checklist before a project proceeds. Table 2-9 presents a summary of how NNSA/NFO complied with NEPA in 2014.

In 2013, NNSA/NFO (then the Nevada Site Office [NSO]) completed the final *Site-Wide Environmental Impact Statement for the Nevada National Security Site and Offsite Locations in Nevada* (NNS SWEIS) (NNSA/NSO 2013). The final NNS SWEIS identifies NNSA’s preferred alternative as a hybrid alternative comprising various programs, capabilities, projects, and activities selected from among the three alternatives. A Record of Decision that identified NNSA’s preferred alternative was published on December 20, 2014. The final NNS SWEIS replaces the previous programmatic NNS EIS (DOE/NV 1996) and address impacts from NNSA/NFO operations in Nevada for the 10-year period beginning on December 20, 2014.

In 2014, NNSA/NFO completed the *NNSA/NFO NEPA Annual Planning Document*, which was submitted to DOE HQ in January 2015. It provides the status of all EAs and EISs being developed or planned in the next 12–24 months and the budget and major milestone information for the NNS SWEIS.

Table 2-9. NNS NEPA compliance activities conducted in FY 2014

Results of NEPA Checklist Reviews/NEPA Compliance Activities
31 NEPA Checklists were reviewed
10 projects were exempted from further NEPA analysis because they were of CX status.
21 projects were exempted from further NEPA analysis due to their inclusion under previous analysis in the NNS EIS (DOE/NV 1996) and it’s Record of Decision.

2.8 *Historic Preservation and Cultural Resource Protection*

2.8.1 *Applicable Regulations*

National Historic Preservation Act of 1966, as amended – This act presents the goals of federal participation in historic preservation and delineates the framework for federal activities. Section 106 requires federal agencies to take into account the effects of their undertakings on properties included in, or eligible for inclusion in, the National Register of Historic Places (NRHP) and to consult with interested parties. The Section 106 process involves the agency reviewing background information, identifying eligible properties for the NRHP within the area of potential effect through consultation with the Nevada State Historic Preservation Office (SHPO), making a determination of effect (when applicable), and developing a mitigation plan when an adverse effect is unavoidable. Determinations of eligibility, effect, and mitigation are conducted in consultation with the SHPO and, in some cases, the federal Advisory Council on Historic Preservation. Section 110 sets out the broad historic preservation responsibilities of federal agencies and is intended to ensure that historic preservation is fully integrated into the ongoing programs of all federal agencies. It requires federal agencies to develop and implement a Cultural Resources Management Plan, to identify and evaluate the eligibility of historic properties for long-term management as well as for future project-specific planning, and to maintain archaeological collections and their associated records at professional standards. At the NNS, a long-term management strategy includes (1) monitoring NRHP-listed and eligible properties to determine if environmental or other actions are negatively affecting the integrity or other aspects of eligibility and (2) taking corrective actions if necessary.

EO 11593, *Protection and Enhancement of the Cultural Environment* – This EO directs the federal agencies to inventory their cultural resources and establish policies and procedures to ensure the protection, restoration, and maintenance of federally owned sites, structures, and objects of historical, architectural, or archaeological significance.

DOE Policy DOE P 141.1, *Department of Energy Management of Cultural Resources* – The purpose of this policy is to ensure that DOE programs, including the NNSA, integrate cultural resources management into their missions and activities.

Archaeological Resources and Protection Act of 1979 – The purpose of this act is to secure, for the present and future benefit of the American people, the protection of archaeological resources and sites that are on public and American Indian lands, and to address the irreplaceable heritage of archaeological sites and materials. It requires the issuance of a federal archaeology permit to qualified archaeologists for any work that involves inventory, excavation or removal of archaeological resources on federal and American Indian lands and notification to American Indian tribes of these activities. Unauthorized excavation, removal, damage, alteration, or defacement of archaeological resources is prohibited, as is the sale, purchase, exchange, transport, receipt of, or offer for sale of such resources. Criminal and civil penalties apply to such actions. Information concerning the nature and location of any archaeological resource may not be made available to the public unless the federal land manager determines that the disclosure would not create a risk of harm to the resources or site. The Secretary of the Interior is required to submit an annual report at the end of each fiscal year to Congress that reports the scope and effectiveness of all federal agencies' efforts on the protection of archaeological resources, specific projects surveyed, resources excavated or removed, damage or alterations to sites, criminal and civil violations, the results of permitted archaeological activities, and the costs incurred by the federal government to conduct this work. All archaeologists working at the NNS must have qualifications that meet federal standards and must work under a permit issued by NNSA/NFO. In the event of vandalism, NNSA/NFO would need to investigate the actions.

American Indian Religious Freedom Act of 1978 – This law established the government policy to protect and preserve for American Indians their inherent right of freedom to believe, express, and exercise the traditional religions, including but not limited to access to sites, use and possession of sacred objects, and the freedom to worship through ceremonial and traditional rites. Locations exist on the NNS that have religious significance to Western Shoshone and Southern Paiute; visits to these places involve prayer and other activities. Access is provided by NNSA/NFO as long as there are no safety or health hazards.

Native American Graves Protection and Repatriation Act (NAGPRA) of 1990 – This act requires federal agencies to identify Native American human remains, funerary objects, sacred objects, and objects of cultural patrimony in their possession. Agencies are required to prepare an inventory of human remains and associated funerary objects, as well as a summary with a general description of sacred objects, objects of cultural patrimony, and unassociated funerary objects. Through consultation with Native American tribes, the affiliation of the remains and objects is determined, and the tribes can request repatriation of their cultural items. The agency is required to publish a notice of inventory completion in the Federal Register. The NNSS artifact collection is subject to NAGPRA.

2.8.2 Reporting Requirements

NNSA/NFO submits Section 106 cultural resources inventory reports and historical evaluations to the Nevada SHPO for review and concurrence. Mitigation plans and mitigation documents are also submitted to the Nevada SHPO, and some types of documents go to the Advisory Council on Historic Preservation and the National Park Service. Reports containing data on site locations are not available to the public. Some technical reports, however, are available to the public upon request and can be obtained from the Office of Scientific and Technical Information. The 2014 reports submitted to agencies are discussed in Chapter 14.

Table 2-10. NNSS compliance status with applicable historic preservation regulations

Requirement	2014 Compliance Status	Section Reference ^{e(a)}
National Historic Preservation Act of 1966; EO 11593, <i>Protection and Enhancement of the Cultural Environment</i>; and DOE P 141.1, <i>Department of Energy Management of Cultural Resources</i>		
Maintain and implement NNSS Cultural Resources Management Plan	Compliant	14.0
Conduct cultural resources inventories and evaluations of historic structures	Compliant	14.1; 14.2
Make determinations of eligibility to the National Register	Compliant	14.1; 14.2
Make assessments of impact to eligible properties	Compliant	14.1
Manage artifact collection in accordance with required professional standards	Compliant	14.5
Archaeological Resources and Protection Act of 1979		
Conduct archaeological work by qualified personnel	Compliant	14.0
Document occurrences of damage to archaeological sites	Compliant	14.1
Complete and submit Secretary of the Interior Archaeology Questionnaire	Compliant	14.4
American Indian Religious Freedom Act of 1978		
Allow American Indians access to NNSS locations for ceremonies and traditional use	Compliant	14.6
Native American Graves Protection and Repatriation Act		
Consult with affiliated American Indian tribes regarding repatriation of cultural items	Compliant	14.6
Overall Requirement		
Consult with tribes regarding various cultural resources issues	Compliant	14.6

2.9 Conservation and Protection of Biota and Wildlife Habitat

2.9.1 Applicable Regulations

Endangered Species Act (ESA) – Section 7 of this act requires federal agencies to ensure that their actions do not jeopardize the continued existence of federally listed endangered or threatened species or their critical habitat. The threatened desert tortoise is the only animal protected under the ESA that may be impacted by NNSS operations. NNSS activities within tortoise habitat are conducted so as to comply with the terms and conditions of Biological Opinions issued by the U.S. Fish and Wildlife Service (FWS) to NNSA/NFO (FWS 2009).

Migratory Bird Treaty Act (MBTA) – This act prohibits the harming of any migratory bird, their nest, or eggs without authorization by the Secretary of the Interior. All but 5 of the 239 bird species observed on the NNSS are protected under this act. Biological surveys are conducted for projects to prevent direct harm to protected birds, nests, and eggs. Biologists periodically collect game birds for radiological analysis under a federal migratory bird collection permit.

Bald and Golden Eagle Protection Act – This act prohibits the capture or harming of bald and golden eagles without special authorization. Both bald and golden eagles occur on the NNSS. Biological surveys are conducted for projects to prevent direct harm to eagles and their nests and eggs.

Wild Free-Roaming Horse and Burro Act – This act makes it unlawful to harm wild horses and burros. It requires the U.S. Bureau of Land Management (BLM) to protect, manage, and control wild horses and burros within designated herd management areas (HMAs) in a manner that is designed to achieve and maintain a thriving natural ecological balance. Although the NNSS is not within an active HMA, a Five-Party Cooperative Agreement exists between NNSA/NFO, NTTR, FWS, BLM, and the State of Nevada Clearinghouse that calls for cooperation in conducting resource inventories and developing resource management plans for wild horses and burros and maintaining favorable habitat for them on federally withdrawn lands. BLM considers the NNSS a zero herd-size management area. NNSA/NFO consults with BLM regarding any issue of NNSS horse management. Biologists conduct periodic horse census surveys on the NNSS.

Clean Water Act (CWA), Section 404, Wetlands Regulations – This act regulates land development affecting wetlands by requiring a permit obtained from the U.S. Army Corps of Engineers (USACE) to discharge dredged or fill material into waters of the United States, which includes most wetlands on public and private land. NNSS projects are evaluated for their potential to disturb wetlands and their need for a Section 404 permit application. Based on recent rulings, no natural NNSS wetland may meet the criteria of a “jurisdictional” wetland subject to Section 404 regulations. However, final determination from the USACE regarding the status of NNSS wetlands has yet to be received.

National Wildlife Refuge System Administration Act – This act forbids a person to knowingly disturb or injure vegetation or kill vertebrate or invertebrate animals or their nests or eggs on any National Wildlife Refuge lands unless permitted by the Secretary of the Interior. The boundary of the Desert National Wildlife Refuge (DNWR), land administered within this system, is approximately 5 kilometers (3.1 miles) downwind of the NPTEC in Area 5. In the past, biological monitoring was conducted to verify that tests conducted at the NPTEC do not disperse toxic chemicals that could harm biota on the DNWR. However, no tests in the past ten years used, and no future tests plan to use chemicals in quantities or toxicity warranting field monitoring. Under the NNSS SWEIS (NNSA/NSO 2013), monitoring was not included as a mitigation requirement for NPTEC tests and no actions were identified for NNSA/NFO to take regarding compliance with this Act.

EO 11990, Protection of Wetlands – This EO requires governmental agencies to minimize the destruction, loss, or degradation of wetlands and to preserve and enhance the natural and beneficial values of wetlands in carrying out the agency’s responsibilities, including managing federal lands and facilities. Projects are evaluated for their potential to disturb the natural water sources on the NNSS. NNSS wetlands are monitored to document their status and use by wildlife, even though they may not meet the criteria for “jurisdictional” status under the CWA.

EO 11988, Floodplain Management – This EO ensures protection of property and human well-being within a floodplain and protection of floodplains themselves. The Federal Emergency Management Agency publishes guidelines and specifications for assessing alluvial fan flooding. NNSA/NFO generally satisfies EO 11988 through DOE O 420.1B, “Facility Safety,” and invoked standards. DOE O 420.1B and the associated implementation guide for mitigation of natural phenomena hazards call for a graded approach to assessing risk to all facilities (structures, systems, and components [SSC]) from potential natural hazards. Chapter 4 of DOE-STD-1020-2002, “Natural Phenomena Hazards Design and Evaluation Criteria for Department of Energy Facilities,” provides flood design and evaluation criteria for SSC. Evaluations of flood hazards at the NNSS are generally conducted to ensure protection of property and human well-being.

EO 13186, Responsibilities of Federal Agencies to Protect Migratory Birds – This EO directs federal agencies to take certain actions to further implement the MBTA if agencies have, or are likely to have, a measurable negative effect on migratory bird populations. It also directs federal agencies to support the conservation intent of the MBTA and conduct actions, as practicable, to benefit the health of migratory bird populations. NNSS projects are evaluated for their potential to impact such bird populations.

EO 13112, Invasive Species – This EO directs federal agencies to act to prevent the introduction of, or to monitor and control, invasive (non-native) species; to provide for restoration of native species; and to exercise care in taking actions that could promote the introduction or spread of invasive species. Land-disturbing activities on the NNSS have resulted in the spread of numerous invasive plant species. Habitat reclamation and other controls are evaluated and conducted, when feasible, to control such species and meet the purposes of this EO.

DOE O 458.1, Radiation Protection of the Public and the Environment – This order, approved in June 2011, requires the establishment and implementation of procedures and practices to ensure that populations of terrestrial plants and aquatic and terrestrial animals within local ecosystems are protected. This order specifically addresses their protection from any radiological impacts of DOE/NNSA activities (see Section 2.4.1). Ecosystem mapping and surveys for protected and important species are conducted on the NNSS to identify the biota and ecosystems that may be impacted by both radiological and other NNSS activities.

NAC 503.010–503.104, Protection of Wildlife – This code identifies Nevada animal species, both protected and unprotected, and prohibits the harm of protected species without special permit. Biologists periodically conduct live trapping and release of bats, rodents, reptiles, and desert tortoises under a state wildlife handling permit. Over 200 bird species, 1 reptile species, 6 bat species, and 2 small mammal species on the NNSS are state-protected. Biological surveys are conducted for projects to prevent direct harm to protected birds, nests, eggs, and protected animals.

NAC 527, Protection and Preservation of Timbered Lands, Trees and Flora – This code requires that the State Forester Firewarden determine the protective status of Nevada plants and prohibits removal or destruction of protected plants without special permit. Currently, no state-protected plants are known to occur on the NNSS. Annual reviews of the status of NNSS plants are conducted.

2.9.2 Compliance Reports

The following reports were prepared in 2014 or 2015 to meet regulation requirements or to document compliance for all activities conducted in 2014:

- *Annual Report of Actions Taken under Authorization of the Biological Opinion on NNSS Activities (File Nos. 84320-2008-F-0416 and 84320-2008-B-0015) – January 1, 2014, through December 31, 2014*, submitted to FWS Las Vegas Office
- *Annual Report for Handling Permit S36422*, submitted to Nevada Division of Wildlife
- *Annual Report for Federal Migratory Bird Scientific Collecting Permit SCCL-008695-0*, submitted to FWS Sacramento Office

Table 2-11. NNSS compliance status with applicable biota and wildlife habitat regulations

Requirement	Compliance Limit	2014 Compliance Status	Section Reference ^(a)
Endangered Species Act – 1996 Opinion for NNSS Programmatic Activities			
Track the number of tortoises accidentally injured or killed due to NNSS activities and the number captured and displaced from project sites	Limit varies by project/activity	Compliant	15.1; Table 15-1
Track the number of tortoises taken by way of injury or mortality on NNSS paved roads by vehicles other than those in use during a project	4 per year not to exceed 15 by 2019	Compliant	15.1; Table 15-1
Track the number of total acres (ac) of desert tortoise habitat disturbed during NNSS project construction from 2009 to 2019	2,710 ac	Compliant	15.1; Table 15-1
Follow all terms and conditions of the Biological Opinion during construction and operation of NNSS projects	NA ^(b)	Compliant	15.1
Conduct biological surveys at proposed project sites to assess presence of protected species	NA	Compliant	15.2
Migratory Bird Treaty Act			
Prevent the harm of migratory birds, their nests, and their eggs from NNSS project activities	0	7 accidental bird deaths	15.3; Table 15-2; Figure 15-2
National Wildlife Refuge System Administration Act			
Avoid killing or destroying animals, their nests, or eggs and disturbing or injuring vegetation on System lands (the DNWR) as a result of NNSS activities	0	Compliant	4.2.10
Wild Free-Roaming Horse and Burro Act and Five-Party Cooperative Agreement			
Avoid harassing or killing wild horses due to NNSS activities	0	Compliant	15.3; Table 15-2
Cooperate in conducting resource inventories and developing resource management plans for horses on the NNSS, NTTR, and DNWR	NA	Compliant	15.3; Table 15-2
EO 11988, Floodplain Management			
Conduct flood hazard assessments	NA	NA – No floodplain projects	--
Clean Water Act, Section 404 – Wetlands Regulations and EO 11990, “Protection of Wetlands”			
Track the number of wetlands disturbed by NNSS activity	NA	0	15.3; Table 15-2
EO 13112, Invasive Species			
Evaluate feasibility of conducting habitat reclamation and other controls to control spread of invasive species	NA	Compliant	15.4
NAC 503.010–503.104 and NAC 527 – Nevada Protective Measures for Wildlife and Flora			
Track the number of state-protected animals harmed, killed, or collected and the number of state-protected plants harmed or collected due to NNSS activities	Without special permit: 0 Under permit: 10 collections each per year of jackrabbits, cottontail rabbits, mourning doves, chukar, quail, and 15 of selected bat species Unlimited capture/releases of bats, rodents, reptiles	Compliant	--

(a) The sections within this document that discuss the compliance summary data

(b) Not applicable

2.10 Occurrences, Unplanned Releases, and Continuous Releases

2.10.1 Applicable Regulations

Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) – Continuous release reporting under Section 103 requires that a non-permitted hazardous substance release that is equal to or greater than its reportable quantity be reported to the National Response Center. The EPA requires all facilities that release a hazardous substance meeting the Section 103(f) requirements to report annually to the EPA and perform an annual evaluation of releases. CERCLA requirements applicable to NNSS operations also pertain to an emergency response program for hazardous substance releases to the environment (see discussion of EPCRA in Section 2.5).

Emergency Planning and Community Right-to-Know Act (EPCRA) – This act is described in Section 2.5. See Table 2-5 for a summary of compliance to EPCRA pertaining to unplanned environmental releases of hazardous substances.

40 CFR 302.1–302.8, “Designation, Reportable Quantities, and Notification” – This CFR requires facilities to notify federal authorities of spills or releases of certain hazardous substances designated under CERCLA and the CWA. It specifies what quantities of hazardous substance spills/releases must be reported to authorities and delineates the notification procedures for a release that equals or exceeds the reportable quantities.

DOE O 232.2, Occurrence Reporting and Processing of Operations Information – This order requires that DOE and NNSA be informed about events within ten operational categories (Operational Emergencies, Personnel Safety and Health, Environmental, Contamination Radiation Control, etc.) that could adversely affect the health and safety of the public, workers, environment, DOE missions, or the credibility of the DOE. Within the Environmental category, it sets reporting criteria for unplanned environmental releases of pollutants, hazardous substances, extremely hazardous substances, petroleum products, and sulfur hexafluoride at DOE/NNSA sites/facilities. Within the Noncompliance Notifications category, it also requires sites/facilities to report to DOE/NNSA any written notification received from an outside regulatory agency that the site/facility is in noncompliance with a schedule or requirement.

NAC 445A.345–445.348, Notification of Release of Hazardous Substance – This NAC requires state notification for the unplanned or accidental releases of specified quantities of pollutants, hazardous wastes, and contaminants.

Water Pollution Control General Permit GNEV93001 – This general wastewater discharge permit issued by the State to the NNSS specifies that no petroleum products will be discharged into treatment works without first being processed through an oil/water separator or other approved method. It also specifies how NNSA/NFO shall report each bypass, spill, upset, overflow, or release of treated or untreated sewage.

Other NNSS Permits/Agreements – As with General Permit GNEV93001, other state permits and agreements are cited in previous subsections of this chapter (e.g., FFACO) that specify that accidents or events of non-compliance must be reported. These include events that may create an environmental hazard.

2.10.2 Compliance Status

There are no continuous releases on the NNSS or at the NLVF and RSL-Nellis. Three reportable environmental occurrences happened in 2014 (Table 2-12). During 2014, there were 22 additional spills at the NNSS, none of which met regulatory agency reporting criteria. They consisted of small-volume releases either to containment areas or to other surfaces. All spills were cleaned up.

Table 2-12. Environmental occurrences in 2014

Description of Occurrence	Reporting Criteria ^(a)	Corrective Actions Taken
Report Number/Date of Occurrence: EM--NVSO-NST-NTS-2014-0001, January 16, 2014		
<p>On January 15, 2014, radiological control technicians were performing pre-work radiological surveys and collecting sediment samples in an unoccupied area for the Underground Test Area Waste Water Disposal Study at the U-19ad PS#1A site in Area 19 of the NNSS and discovered fixed beta-gamma contamination at a maximum level of 100,000 dpm/100cm² at a lined sump. There was no alpha or removable beta-gamma contamination detected in the sump or on the liner.</p>	<p>6B(4) Identification of onsite radioactive contamination greater than 10 times the total contamination values in 10 CFR 835 Appendix D (exclusive of footnote 3), and that is found outside of areas routinely posted, controlled and monitored for radiological contamination, and areas controlled in accordance with 10 CFR 835.1102(c). For tritium, the reporting threshold is 10 times the removable contamination values in 10 CFR Part 835, Appendix D.</p>	<p>Operations were discontinued and area was properly posted as a Radioactive Material Area.</p>
Report Number/Date of Occurrence: NA--NVSO-NST-NTS-2014-0014, July 2, 2014		
<p>On July 2, 2014, NSTec determined that an emergency generator in Area 6 of the NNSS exceeded NDEP air permit requirements by operating more than the allowed 100 hours annually in nonemergency situations. The generator turned itself on and it is unknown what caused the generator to startup.</p>	<p>5A(2) - Any release (onsite or offsite) of a pollutant from a DOE facility that is above levels or limits specified by outside agencies in a permit, license, or equivalent authorization, when reporting is required in a format other than routine periodic reports.</p>	<p>NSTec verbally notified NDEP's Bureau of Air Pollution Control; emergency generator was shut down.</p>
<p>On October 3, 2014, NNSA/NFO received a warning notice from Nevada's Bureau of Air Pollution Control for exceeding the permitted hours of operation limit.</p>	<p>9(1) - Any written notification from an outside regulatory agency that a site/facility is considered to be in noncompliance with a schedule or requirement.</p>	
Report Number/Date of Occurrence: EM--NVSO-NST-NTS-2014-0022, December 30, 2014		
<p>On December 30, 2014, NSTec received notifications that Nuclear Fuel Services (NFS) received a formal Notice of Violation from the State of Tennessee for five drums sent to NNSS in 2013 and 2014 that contained chromium, a RCRA hazardous waste. When the drums were shipped and received, they were characterized as low-level waste in accordance with the approved profile. It was later determined by NFS that the five drums contained chromium. The drums are currently buried in a non-RCRA regulated low-level waste disposal cell at the NNSS that operates under a solid waste permit.</p>	<p>10(2) - An event, condition, or series of events that does not meet any of the other reporting criteria, but is determined by the Facility Manager or line management to be of safety significance or of concern for that facility or other facilities or activities in the DOE complex.</p>	<p>NSTec notified NNSA/NFO. Corrective actions are pending until final resolution of the NFS containers is determined.</p>

(a) Reporting requirements provided in DOE O 232.2 can be found at <https://www.directives.doe.gov/old-site/directives/0232.2-BOrder/view>, as accessed on February 2, 2015.

2.11 Environment, Safety, and Health Reporting

2.11.1 Applicable Regulations

DOE O 231.1B, Environment, Safety and Health Reporting – This order calls for the “timely collection, reporting, analysis, and dissemination of information on environment, safety, and health issues as required by law or regulations or as needed to ensure that the DOE and the NNSA are kept fully informed on a timely basis about events that could adversely affect the health and safety of the public or the workers, the environment, the intended purpose of DOE facilities, or the credibility of the Department.” The order specifically requires DOE and NNSA sites to prepare an annual calendar year report, referred to as the Annual Site Environmental Report (ASER).

The data to be included in an ASER are air emissions, effluent releases, environmental monitoring, and estimated radiological doses to the public from releases of radioactive material at DOE or NNSA sites. The annual report must also summarize environmental occurrences and responses reported during the calendar year, confirm compliance with environmental standards and requirements, and highlight significant programs and efforts. Environmental performance indicators and/or performance measures programs are to be included. The breadth and detail of this reporting should reflect the size and extent of programs at a particular site. The ASER for the calendar year is to be completed and made available to the public by October 1 of the following year. DOE’s Office of Analysis is to issue annual guidance to all field elements regarding the preparation of the report.

For NNSA/NFO, reporting is accomplished through the publication of the NNSS ASER, which is titled the Nevada National Security Site Environmental Report (NNSSER).

2.11.2 Compliance Status

In 2014, the NNSSER was published under the title *Nevada National Security Site Environmental Report 2013* (NSTec 2014c). It was published and posted on the NNSA/NFO and DOE Office of Scientific and Technical Information websites by September 9, 2014. All individuals on distribution received an e-mail notification on September 10, 2014 concerning its availability on the internet. Additionally, hardcopies of the full NNSSER, a 24-page NNSSER Summary, and a compact disc containing all 2013 NNSSER products were mailed to individuals requesting the products by October 9, 2014.

2.12 Summary of Permits

Table 2-13 presents the complete list of all federal and state permits active during CY 2014 for NNSS, NLVF, and RSL-Nellis operations and that have been referenced in previous subsections of this chapter. The table includes those pertaining to air quality monitoring, operation of drinking water and sewage systems, hazardous materials and HW management and disposal, and endangered species protection. Some 2013 permit names retain the “NTS” acronym for the NNSS because they have not been officially changed with the regulatory agencies. Reports associated with permits are submitted to the appropriate designated state or federal office. Copies of reports may be obtained upon request.

Table 2-13. Environmental permits required for NNSA/NFO operations at NNSS, NLVF, and RSL-Nellis

Permit Number	Permit Name or Description	Expiration Date	Reporting
Air Quality			
NNSS			
AP9711-2557	NNSS Class II Air Quality Operating Permit	June 25, 2014 (permit renewal submitted April, 2014)	Annually
13-47 and 14-52	NNSS Open Burn Authorization, Fire Extinguisher Training (Various Locations)	March 19, 2014/ March 20, 2015	None
13-48 and 14-51	NNSS Open Burn Authorization, Simulated Vehicle Burns, A-23, Facility #23-T00200 (NNSS Fire & Rescue Training Center)	March 19, 2014/ March 20, 2015	None

Table 2-13. Environmental permits required for NNSA/NFO operations at NNSS, NLVF, and RSL-Nellis (continued)

Permit Number	Permit Name or Description	Expiration Date	Reporting
Air Quality			
NNSS			
14-82	NNSS Open Burn Authorization, Fire Extinguisher Training (BullEx Propane System), A-1, A-6, A-23, Facility #23-T00200 (NNSS Fire & Rescue Training Center)	June 30, 2014/ March 20, 2015	None
AP9711-2659	NTTR Class II Air Quality Operating Permit, Surface Area Disturbance, Wells ER-EC-13 and ER-EC-15	March 5, 2015	Annually

Chapter 3: Environmental Management System

Coby P. Moke and Dawn M. Starrett

National Security Technologies, LLC

The U.S. Department of Energy, National Nuclear Security Administration Nevada Field Office (NNSA/NFO) conducts activities on the Nevada National Security Site (NNSS) while ensuring the protection of the environment, the worker, and the public. This is accomplished, in part, through the implementation of an Environmental Management System (EMS). An EMS is a business management practice that incorporates concern for environmental performance throughout an organization, with the ultimate goal being continual reduction of the organization's impact on the environment. An EMS ensures that environmental issues are systematically identified, controlled, and monitored, and it provides mechanisms for responding to changing environmental conditions and requirements, reporting on environmental performance, and reinforcing continual improvement. National Security Technologies, LLC (NSTec), the current Management and Operating contractor for the NNSS, designed an EMS to meet the 17 requirements of the globally recognized International Organization for Standardization (ISO) 14001:2004 Environmental Management Standard. The EMS was re-certified in 2014 for another 3-year period.

The EMS incorporates environmental stewardship goals that are identified in federal EMS directives applicable to all U.S. Department of Energy (DOE) and U.S. Department of Energy, National Nuclear Security Administration (NNSA) sites. In 2014, they included DOE Order DOE O 436.1A, "Departmental Sustainability"; Executive Order EO 13423, "Strengthening Federal Environmental, Energy, and Transportation Management"; and EO 13514, "Federal Leadership in Environmental, Energy, and Economic Performance" (see Section 2.1). This chapter describes the 2014 progress made towards improving overall environmental performance and meeting sustainable environmental stewardship goals. Reported progress applies to operations on the NNSS as well as support activities conducted at the NNSA/NFO-managed North Las Vegas Facility (NLVF) and Remote Sensing Laboratory–Nellis (RSL–Nellis). NNSA/NFO uses this annual environmental report as the mechanism to communicate to the public the components and status of the EMS, which is a requirement for ISO 14001:2004 certification.

3.1 Environmental Policy

The NSTec environmental policy, approved by NNSA/NFO, contains the following key goals and commitments:

- Protect environmental quality and human welfare by implementing EMS practices.
- Identify and comply with all applicable DOE orders and federal, state, and local environmental laws and regulations.
- Identify and mitigate environmental aspects early in project planning.
- Establish environmental objectives, targets, and performance measures.
- Collaborate with employees, customers, subcontractors, and key suppliers on sustainable development and pollution prevention efforts.
- Communicate and instill an organizational commitment to environmental excellence in company activities through processes of continual improvement.

3.2 Environmental Aspects

Operations are evaluated to determine if they have an environmental aspect, and the EMS is implemented to minimize or eliminate any potential impacts. Operations are evaluated by performing Hazard Assessments, preparing Health and Safety Plans and Execution Plans, and preparing and reviewing National Environmental Policy Act documents. A list of aspects is compiled, and they are ranked in order of importance to determine which aspects are significant. The factors that are considered during ranking are the potential to cause adverse environmental impact; the potential for noncompliance with regulations; the ability to meet permit requirements, contract and performance objectives, and DOE order requirements; and the potential to result in bad publicity. The likelihood of occurrence and severity of each of these factors is considered. The significant aspects compose approximately the top half of the list. This process is done annually to account for changing activities, regulations/DOE orders, and management priorities. For 2014, the following list of environmental aspects were identified.

Significant aspects:

- Air quality
- Drinking water quality
- Energy and fuel use
- Environmental restoration
- Industrial chemical storage and use
- Greenhouse gas emissions
- Groundwater protection
- Hazardous, radioactive, and mixed waste management (generation, storage, and disposal)
- Wastewater management (generation and disposal)
- Resource protection (cultural, biological, and raw materials)

Other aspects:

- Building construction and renovation
- Electronics stewardship
- Nonhazardous waste management (generation, storage, and disposal)
- Purchase of materials and equipment
- Recycling and management of surplus property and materials
- Water use
- Surface water and stormwater runoff

3.3 Environmental Objectives, Targets, and Sustainability Goals

To address the identified significant environmental aspects of NNSA/NFO operations, an Environmental Working Group (EWG) selects objectives and targets that are determined on a fiscal year (FY) (October 1 through September 30) basis. Targets are tracked by the various responsible operational groups, and reported quarterly to NNSA/NFO. The majority of objectives and targets identified each FY are identical to the environmental sustainability goals of DOE O 436.1A, EO 13514, and EO 13423 (Table 3-1), which are tracked by the Energy Management Program (EMP) and the Pollution Prevention and Waste Minimization (P2/WM) Program, each described in the subsections below.

Two EMS targets were identified for FY 2014 in addition to the sustainability goals presented in Table 3-1. One was to identify opportunities to increase the diversion of solid wastes from the Mercury landfill. The second additional target was to identify biobased and Environmentally Preferable Products (EPP) for purchase that are substitutes for non-EPP, non-biobased products currently being used and which are readily available, affordable, and effective. Both of these FY 2014 targets, which relate to P2/WM activities, are discussed in Section 3.3.2.

3.3.1 Energy Management Program

The EMP strives to ensure continuous life-cycle, cost-effective improvements to increase energy efficiency; increase the effective management of energy, water, and transportation fleets; and increase the use of clean energy sources for NNSA/NFO operations. NNSA/NFO currently uses electricity, fuel oil, and propane at the NNSS and RSL-Nellis facilities. At the NLVF, electricity, fuel oil, and natural gas are used. NNSA/NFO vehicles and equipment are powered by unleaded gasoline, diesel, bio-diesel, E-85, and jet fuel. All water used at the NNSS is groundwater, and water used at the NLVF and RSL-Nellis is predominately surface water from Lake Mead.

Each FY, the EMP produces a fiscal year NNSA/NFO Site Sustainability Plan (SSP) (NSTec 2014a) that identifies how NNSA/NFO will help meet DOE's complex-wide site sustainability goals, which were first published in the 2010 Strategic Sustainability Performance Plan (SSPP) (DOE 2010). The SSP also satisfies the requirement of EO 13423 for an Energy Management Plan. The SSP describes the program, planning, and budget assumptions as well as NNSA/NFO's performance status for the previous year for each DOE SSPP goal, and planned actions to meet each goal during the next year. To implement the SSP, an Energy Management Council (EMC) meets monthly to discuss the requirements and track and facilitate their completion. The EMC and the EWG coordinate to ensure that all EMS-tracked objectives and targets mirror overlapping annual goals in the SSP. Table 3-1 includes a summary of the DOE SSPP goals and NNSA/NFO's FY 2014 status in reaching them. DOE reports complex-wide progress toward the site sustainability goals in an annually produced SSPP (DOE 2014).

Table 3-1. Environmental sustainability goals and FY 2014 performance status

DOE Agency SSPP Goal ^(a) (from DOE 2014)	NNSA/NFO Performance Status (from NSTec 2014)
Targets highlighted in green have been met or exceeded	
Goal 1: Greenhouse Gas (GHG) Reduction	
28% reduction of Scope 1 and 2 GHG emissions ^(b) by FY 2020, from an FY 2008 baseline	FY 2014 emissions were 46,725 MtCO ₂ e ^(c) , a 1.5% decrease from the FY 2008 baseline of 47,454 MtCO ₂ e.
13% reduction in Scope 3 ^(b) GHG emissions by FY 2020, from an FY 2008 baseline	FY 2014 emissions were determined to be 20,032 MtCO ₂ e, a 39% increase from the FY 2008 baseline of 14,398 MtCO ₂ e. Also in FY 2014, the FY 2013 Scope 3 GHG emissions were recalculated and determined to be 19,817 MtCO ₂ e instead of 6,694 MtCO ₂ e, which were reported in NSTec (2014b).
Goal 2: Sustainable Buildings	
30% reduction of energy intensity (BTUs per square foot of building space) by FY 2015, from an FY 2003 baseline	In FY 2014, energy intensity was reduced overall by 29.5% from the FY 2003 baseline.
Energy and water assessments conducted for 25% of all facilities covered under Section 432 of the Energy Independence and Security Act to ensure that 100% of covered facilities are assessed every 4 years	In FY 2014, 46 energy audits/assessments were conducted, meeting this goal; the audits/assessments identified energy conservation measures for several buildings at the NNSA and NLVF.
Metering of individual buildings or processes for 90% of electricity (by October 2012) and for 90% of steam, natural gas, and chilled water (by October 2015)	77% of electricity is metered ^(d) , 80% of natural gas is metered, 67% of chilled water is metered, 20% of water is metered, and no steam is used.
Cool roofs (see Glossary, Appendix B), unless determined uneconomical, for roof replacements; new roofs must have a thermal resistance of at least R-30	One building, Building A-13, totaling 21,819 gross square feet (gsf) of space, had a cool roof installed in FY 2014. No other new roofs were installed.
All new construction, major renovations, and alterations of buildings larger than 5,000 gsf are to comply with the Guiding Principles (GPs) for Federal Leadership in High Performance Sustainable Buildings design (Interagency Sustainability Working Group 2008); all buildings for which such work is greater than \$5 million are to achieve the U.S. Green Building Council's Leadership in Energy and Environmental Design Gold certification (unless determined not to be cost effective by the Senior Acquisition Official).	No such construction or major renovations occurred in FY 2014, and no new construction/renovations are planned for FY 2015.
15% of existing buildings larger than 5,000 gsf to be compliant with the GPs by FY 2015	In 2014, NNSA/NFO operated 118 enduring buildings larger than 5,000 gsf; 18 of them (15%) have been identified for modifications to meet the goal; 4 of the 118 (3.4%) currently meet the GPs, and the other 14 range from 69% to 85% complete toward meeting the GPs.
Goal 3: Fleet Management	
10% annual increase in fleet alternative fuel consumption by FY 2015, relative to an FY 2005 baseline (FY 2014 target is 136% cumulative increase)	Alternative fuel consumption in FY 2014 was 330,723 gallons (gal), a 164% increase above the FY 2005 baseline of 125,089 gal, exceeding the goal.
2% annual reduction in fleet petroleum consumption by FY 2015, relative to an FY 2005 baseline (FY 2014 target is 18% cumulative decrease)	Petroleum consumption in FY 2014 was 430,621 gal, a 68% reduction from the FY 2005 baseline of 1,328,957 gal, exceeding this goal.
75% of light duty vehicle purchases must consist of alternative fuel vehicles (AFVs) by FY 2000 and thereafter through FY 2014, 100% beginning in FY 2015	98% of all light duty vehicle acquisitions (121) in FY 2014 were AFVs, exceeding this goal.
Goal 4: Water Use Efficiency and Management	
26% reduction in water intensity (gallons used per square foot [gal/ft ²]) by FY 2020 from an FY 2007 baseline	Water intensity ^(e) across all NNSA/NFO facilities was 46.31 gal/ft ² in FY 2014, a 34.2% reduction from the FY 2007 baseline of 70.42 gal/ft ² ^(f) , exceeding this goal.
20% reduction in water consumption of industrial, landscaping, and agricultural water by FY 2020 from an FY 2010 baseline	Non-potable water production ^(f) was 10,692,100 gal in FY 2014, an 80% reduction from the FY 2010 baseline of 54,913,300 gal, exceeding this goal.

Table 3-1. NNSA/NFO Site Sustainability Plan goals and FY 2014 performance status (continued)

DOE Agency SSPP Goal ^(a) (from DOE 2014)	NNSA/NFO Performance Status (from NSTec 2014)
Goal 5: Pollution Prevention and Waste Minimization	
Divert at least 50% of non-hazardous solid waste, excluding construction and demolition materials and debris, from disposal by the end of FY 2015	35% of non-hazardous solid waste was diverted from disposal.
Divert at least 55% of construction and demolition materials and debris from disposal by the end of FY 2015	43% of construction waste was diverted from disposal.
Goal 6: Sustainable Acquisition	
Procurements to meet sustainability requirements and include sustainable acquisition provisions and clauses	Requirements for sustainable acquisition have been incorporated into all applicable subcontracts and company procurement procedures; procurements are reviewed for sustainability requirements to reduce hazardous material use, chemical inventory, GHG emissions, and energy use.
Goal 7: Electronic Stewardship and Data Centers	
Meter 100% of data centers by FY 2015 in order to measure the monthly Power Utilization Effectiveness (PUE) ^(g)	Goal was met in FY 2011; all data centers are metered.
Attain a maximum annual weighted average PUE for data centers of 1.4 by FY 2015 (an ideal PUE is 1.0)	Average PUEs are just over 3 for all data centers ^(h) . Data centers are currently utilizing non-precision cooling solutions, which will not meet this goal by FY 2015. An ESPC ENABLE (see Glossary, Appendix B) contract will be pursued to replace heating, ventilation, and air conditioning (HVAC) systems at the NLVF in an effort to reduce the PUE of the data center in Building C1. Best practices will continue to be implemented to improve PUEs.
100% of eligible personal computers, laptops, and monitors with power management actively implemented and in use by FY 2012	All leased computers and monitors have power management capabilities that are implemented and in use, meeting this goal.
95% of eligible electronics acquisitions that are U.S. Environmental Protection Agency (EPA) Electronic Product Environmental Assessment Tool (EPEAT)-registered	All eligible electronic acquisitions continue to be EPEAT-registered.
Goal 8: Renewable Energy	
20% of a site's annual electricity consumption from renewable sources by FY 2020	1% of power produced on site is from renewable sources; renewable energy credits were purchased, representing 8% of NNSA/NFO's annual electrical consumption. Installation of a planned solar array for the Desert Rock Airport, scheduled for completion by end of FY 2016, will increase NNSA/NFO's onsite renewable energy sources.
Goal 9: Climate Change Resilience	
Address the 2012 DOE Climate Change Adaptation Plan ⁽ⁱ⁾ goals to better understand climate change effects, impacts, vulnerabilities, and risk to DOE programs or sites and to address them (DOE 2012). EO 13514 requires each federal agency to evaluate agency climate change risks and vulnerabilities to identify and manage the effects of climate change on the agency's operations and mission in both the short and long term.	Regional risks to facilities currently identified include drought and flooding. Existing emergency management plans cover flood contingencies. Evaluations of site plans will continue to ensure they are climate change resilient.
Goal 10: Energy Performance Contracts	
Use Energy Performance Contracts (see Glossary, Appendix B), including Energy Savings Performance Contracts (ESPCs) and Utility Energy Service Contracts to obtain energy efficiency investments in buildings and deploy onsite renewable energy through long-term contracts with the private sector, which are paid through savings derived from those investments.	In FY 2014 an ESPC Preliminary Assessment was conducted by Trane, U.S., Incorporated, a qualified energy service company to address the replacement of HVAC units for more energy efficient and less GHG emitting systems. The assessment determined that an ESPC was not currently viable. NNSA/NFO will continue to pursue HVAC replacements, particularly at NLVF in order to reduce the Building C1 data center PUE, through acquisition of an ESPC ENABLE (see Glossary, Appendix B) contract.

(a) These are department-wide goals of the DOE, which NNSA/NFO (or any single DOE site) is not required to specifically meet. NNSA/NFO is committed, however, towards striving to meet these department-wide target goals.

Table 3-1. NNSA/NFO Site Sustainability Plan goals and FY 2013 performance status (continued)

- (b) The GHGs targeted for emission reductions are carbon dioxide, methane, nitrous oxide, hydrofluorocarbons, perfluorocarbons, and sulfur hexafluoride (SF6). Scope 1 GHG emissions include direct emissions from sources that are owned or controlled by a federal agency. Scope 2 includes direct emissions resulting from the generation of electricity, heat, or steam purchased by a federal agency. Scope 3 includes emissions from sources not owned or directly controlled by a federal agency but related to agency activities, such as vendor supply chains, delivery services, employee business air and ground travel, employee commuting, contracted solid waste disposal, contracted waste water discharge, and transmission and distribution losses related to purchased electricity. Fugitive GHG emissions are uncontrolled or unintentional releases from equipment leaks, storage tanks, loading, and unloading.
- (c) MtCO₂e = metric tons of carbon dioxide equivalents.
- (d) The percent of electricity metered was reported as 94% in 2013. The drop in percent is due the discovery that many buildings at the NNSA shared meters; this brought the number of metered buildings from 235 in FY 2013 down to 179 and the total metering percentage from 94% to 77%.
- (e) Water use (i.e., consumption) data for all facilities at the NNSA, needed to compute water intensity, are not available because only a few of the NNSA facilities have water meters installed. Instead, water well production, which is tracked with flow meters on each well, is used to estimate consumption and water intensity on the NNSA. The NLVF and RSL-Nellis buildings all have water meters.
- (f) The FY 2007 water intensity baseline was previously reported to be 90.95 gal/ft² (NSTec 2014b), but that value had erroneously included non-potable water. The FY 2015 SSP (NSTec, 2014a) corrected all water intensity values from 2007–2014 so as to include only potable water production.
- (g) PUE is determined by dividing the amount of power entering a data center by the power used to run the computer infrastructure within it. PUE is expressed as a ratio; efficiency improves as the quotient approaches 1.
- (h) PUEs for the Building C-1 (NLVF) and Building 23-725 (Mercury) data centers were previously reported to be 1.5 and 1.1, respectively (NSTec 2014b). A re-evaluation determined these values were in error.
- (i) This plan is Appendix A of the DOE 2012 Strategic Sustainability Performance Plan (DOE 2012).

3.3.2 Pollution Prevention and Waste Minimization

The P2/WM Program has initiatives to eliminate or reduce the generation of waste, the release of pollutants to the environment, and the use of Class I ozone-depleting substances (ODS). These initiatives are pursued through source reduction, reuse, segregation, and recycling, and by procuring recycled-content materials and environmentally preferable products and services. They also ensure that proposed methods of treatment, storage, and disposal of waste minimize potential threats to human health and the environment. These initiatives address the DOE SSPP goals and the requirements of DOE orders, federal laws, and state regulations applicable to operations at the NNSA, NLVF, and RSL-Nellis (see Section 2.6). The following strategies are employed to meet P2/WM goals.

Source Reduction – The preferred method of waste minimization is source reduction, i.e., to minimize or eliminate waste before it is generated by a project or operation. NNSA/NFO's Integrated Safety Management System requires that every project/operation address waste minimization issues during the planning phase and ensure that adequate funds are allocated to perform any identified waste minimization activities.

Source reduction was the strategy used to implement a requirement under EO 13423 to reduce ODS at all DOE sites. By the end of 2009, NNSA/NFO had discontinued the procurement of Class I ODS for all non-exempted uses, and halon-containing fire extinguishers and equipment were removed from the NNSA and NLVF facilities by 2010. All halons have been removed from RSL-Nellis, with the exception of halon fire extinguishers in the aircraft. Since 2009, only environmentally preferable alternatives to Class I ODS are purchased. All procurement of refrigerants containing ODS (referred to as ODS refrigerants) are approved by the environmental oversight organization, which verifies that only approved products are purchased. Existing ODS refrigerants in equipment are being phased out as equipment is drained for repair or replaced by new equipment with approved alternative refrigerants.

Recycling/Reuse – For some recyclable waste streams generated, NNSA/NFO maintains a recycling program. Items routinely recycled include cardboard; mixed paper (office paper, shredded paper, newspaper, magazine, color print, glossy paper); plastic bottles; plastic grocery bags; elastic/plastic stretch pack; milk jugs; styrofoam; tin and aluminum cans; glass containers; toner cartridges; cafeteria food waste; computers; software; scrap metal; rechargeable batteries; lead-acid batteries; electric lamps (fluorescent, mercury vapor, metal halide, and high-pressure sodium); used oil, antifreeze, and tires. An EMS target identified in FY 2014 was to identify opportunities to increase the diversion of recyclable solid wastes from the Mercury landfill. To accomplish this, an internal management assessment was conducted from May to June 2014 and discovered that not all recyclable cardboard from NNSA Warehouse 23-160 was being recycled. A process developed to correct this was implemented

in June 2014. In 2014, an estimated 35% of all non-hazardous solid wastes were diverted from NNSS landfills and disposal facilities through recycling and reuse.

An Excess Property Program also exists to provide excess property to NNSA/NFO employees or subcontractors, laboratories, other DOE sites, other federal agencies, state and local government agencies, universities, and local schools. If new users are not found, excess property is made available to the public for recycle/reuse through periodic Internet sales. In 2011, an Excess Integrated Project Team was formed with members from radiological operations, materials management, and property management. The team initiated a campaign for disposing reels of cable, drill pipe, drilling equipment, heavy duty equipment, machine shop equipment, and transformers. Since it began, this integrated campaign has generated substantial revenues and extended the life of the NNSS landfill by over three years at a cost savings of \$835,000. In FY 2014, \$1.2 million in revenue was generated.

Environmentally Preferable Purchasing (EPP) – The Resource Conservation and Recovery Act (RCRA), as amended, requires federal agencies to develop and implement an affirmative procurement program (APP). NNSA/NFO maintains an APP that stimulates a market for recycled-content products and closes the loop on recycling. The EPA maintains a list of items containing recycled materials that should be purchased. The EPA determines what the minimum content of recycled material should be for each item. Federal facilities must have a process in place for purchasing the EPA-designated items containing the minimum content of recycled materials. EO 13423 requires federal facilities to ensure, where possible, that 100% of purchases of items on the EPA-designated list contain recycled materials at the specified minimum content. The U.S. Department of Agriculture (USDA) designates types of materials that have a required minimum amount of bio-based chemicals. Products that meet this requirement are being added to procurement lists and tracked.

A 2014 EMS target was to identify biobased and environmentally preferable products that could be purchased as replacements for non-biobased and non-environmentally preferable products if they were readily available, affordable, and effective. As a result, a Biobased Purchasing Catalog of existing Just-in-Time (JIT) items, is in development, and 97 biobased product categories are being added to the procurement system for data tracking and reporting purposes. In October 2014, a USDA BioPreferred report was prepared and documented that during FY 2014, \$1,846.42 was spent on janitorial biobased products.

3.4 Environmental Programs

Multiple programs that serve to protect public health and the environment are implemented on the NNSS (Table 3-2). They address the environmental protection actions supported under the EMS as specified in DOE orders and federal environmental protection statutes. Work conducted in calendar year 2014 by these programs is summarized throughout various chapters of this report (see Table 3-2, “Section Reference” column).

Table 3-2. Major environmental programs of NNSA/NFO

NNSA/NFO Environmental Program	Environmental Protection Action Addressed	Program Description	Section Reference ^(a)
National Environmental Policy Act Compliance	Assess environmental impacts of NNSA/NFO activities	Assesses the environmental effects, values, and reasonable alternatives of proposed projects before deciding to implement any major NNSA/NFO action	Chapter 2: Section 2.7
Routine Radiological Environmental Monitoring Program	Conduct environmental monitoring to detect releases from DOE activities	Monitors direct ambient radiation and monitors man-made radionuclides in air, groundwater, surface water, and biota samples	Chapter 4: Section 4.1; Chapter 5: Section 5.1;
	Estimate contaminant dispersal patterns in the environment	Identifies pathways of exposure to the public	Sections 6, 8, and 9
	Characterize the pathways of exposure to members of the public	Estimates dose to public from NNSA/NFO air emissions, groundwater contamination, direct radiation, and ingestion of NNSS game animals	
	Estimate the exposures and doses to individuals and nearby populations		

Table 3-2. Major environmental programs of NNSA/NFO (continued)

NNSA/NFO Environmental Program	Environmental Protection Action Addressed	Program Description	Section Reference^(a)
Environmental Restoration – Underground Test Area Sites	Conduct environmental monitoring to detect, characterize, and respond to releases to groundwater from DOE activities Estimate contaminant dispersal patterns in the environment	Characterizes radiological groundwater contamination from past NNS activities and develops contaminant flow models needed to design a network of long-term monitoring wells for the protection of public and private water supply wells	Chapter 11: Section 11.1
Environmental Restoration – Industrial Sites	Conduct environmental monitoring to detect, characterize, and respond to releases from DOE activities	Characterizes and remediates contamination from radiological and hazardous wastes or materials located at past NNS industrial sites	Chapter 11: Section 11.2
Environmental Restoration – Soils	Conduct environmental monitoring to detect, characterize, and respond to releases from DOE activities	Characterizes and remediates radiological soil contamination from past NNS activities	Chapter 11: Section 11.3
Community Environmental Monitoring Program	Conduct environmental monitoring to detect releases from DOE activities	Monitors ambient gross alpha and beta radioactivity, gamma radiation, and gamma-emitting radionuclides in offsite community air sampling stations, and tritium in offsite water supply sources	Chapter 7
Radiological Waste Management	Public health and environmental protection and compliance	Manages and safely disposes of low-level waste and mixed low-level waste generated by NNSA/NFO, other DOE, and selected U.S. Department of Defense operations	Chapter 10: Section 10.1
Air Quality Protection (Non-radiological)	Conduct environmental monitoring to detect releases from DOE activities Conform to Nevada’s air quality implementation plan to attain and maintain national ambient air quality standards	Collects and reports air quality data to ensure that NNSA/NFO operations comply with all air quality permits and federal, state, and local standards	Chapter 4: Section 4.2
Water Quality Protection (Non-radiological)	Conduct environmental monitoring to detect releases from DOE activities Comply with water quality standards	Collects and reports drinking water and wastewater quality to ensure that NNSA/NFO operations comply with all water quality permits and federal, state, and local standards	Chapter 5: Section 5.2
Groundwater Protection Program	Implement a site-wide approach for groundwater protection	Integrates site-wide groundwater-related activities across multiple programs	Chapter 13
Hazardous Materials Management	Assist in meeting the chemical emergency planning, release, and reporting requirements of the Emergency Planning and Community Right-to-Know Act and the Pollution Prevention Act of 1990	Safely manages hazardous materials used and stored for NNSA/NFO activities	Chapter 12
Hazardous and Solid Waste Management	Public health and environmental protection and compliance	Safely manages and disposes of hazardous and solid wastes generated by NNSA/NFO operations	Chapter 10: Section 10.2, 10.3, 10.4
Cultural Resources Management Program and Historic Preservation	Assess environmental impacts of NNSA/NFO activities Identify and protect cultural resources	Collects and provides information used to evaluate and mitigate potential impacts of proposed projects on NNS cultural resources and ensures compliance with all state and federal requirements pertaining to cultural resources on the NNS	Chapter 14
Ecological Monitoring and Compliance Program	Assess environmental impacts of NNSA/NFO activities Evaluate the potential impacts to biota in the vicinity of a DOE activity Protect natural resources	Collects ecological information used to evaluate and mitigate potential impacts of proposed projects on NNS ecosystems and biota and ensures compliance with all state and federal requirements to protect NNS biota and habitats	Chapter 15

Table 3-2. Major environmental programs of NNSA/NFO (continued)

NNSA/NFO Environmental Program	Environmental Protection Action Addressed	Program Description	Section Reference ^(a)
Emergency Services and Operations Support – Wildland Fire Management	Protect site resources from wildland fires	Minimizes the vulnerability of NNSS personnel, property, and wildlife to wildland fire damage	Chapter 15: Section 15.5
Meteorological Monitoring	Public health and environmental protection	Conducted by the Air Resources Laboratory, Special Operations and Research Division (SORD) of the National Oceanic and Atmospheric Administration; provides air dispersion and atmospheric sciences support to NNSA/NFO operations at the NNSS and elsewhere, as needed	Section A.3 of <i>Attachment A: Site Description</i> (electronic file included on compact disc of this report); see also SORD website http://www.sord.nv.doe.gov
Quality Assurance Program	Ensure that analytical work for environmental and effluent monitoring supports data quality objectives, using a documented approach for collecting, assessing, and reporting environmental data	Ensures that quality is integrated into the environmental monitoring data collected and analyzed	Chapters 16 and 17

(a) The section(s) within this document that present environmental protection and compliance activities of the listed program

3.5 Legal and Other Requirements

NNSA/NFO and its contractors comply with all applicable laws and regulations. Baseline laws and regulations are supplemented on an activity-specific basis as needed. Operating directives and procedures are developed to meet all legal requirements through controlled processes. Company planning documents, policies, and procedures implement the directives, as applicable. Procedures exist at both the company and organization levels. These documents integrate legal, regulatory, and other company-accepted standards and operating practices into daily work planning and execution activities. Programs conforming to company business management, quality assurance, and environment, safety, and health management processes have been established to ensure that standards are implemented, business objectives are achieved, and the workers, public, and environment are protected.

NNSA/NFO and its contractors operate within the constraints of various federal, state, and local environmental permits. These permits often prescribe operational controls, records management, and monitoring and measuring requirements. Approved operations and maintenance plans may also exist to comply with permit and non-permit regulatory requirements. There are regulatory agreements, agreements in principle between NNSA/NFO and the State of Nevada, memoranda of understanding, and tenant support agreements that are considered in planning and executing work.

3.6 EMS Competence, Training, and Awareness

EMS awareness is included as part of the orientation training required for all new NSTec employees. Ongoing EMS awareness is accomplished by publishing environmental articles in electronic employee newsletters. Focused environmental briefings are given at tail-gate meetings in the field prior to work with high or non-routine environmental risk.

The NNSA/NFO P2/WM initiatives also include an employee and public awareness program. Awareness of P2/WM issues is accomplished by dissemination of articles through electronic mail, contractor and NNSA/NFO newsletters, the maintenance of a P2/WM intranet website, employee training courses, and participation at employee and community events. These activities are intended to increase awareness of P2/WM and environmental issues and highlight the importance of P2/WM for improving environmental conditions in the workplace and community.

3.7 Audits and Operational Assessments

The ISO 14001 certifying organization, Lloyd's Register Quality Assurance (LRQA), conducts semi-annual surveillances on focused portions of the EMS. Findings and recommendations are tracked in the companywide issues tracking system, caWeb. Corrective actions taken to close the issues help to continually improve the EMS program. In January 2014, LRQA conducted a surveillance, and the recertification surveillance was conducted in April. No issues were found, and the EMS was recertified in 2014 for another 3-year period. The EMS Description document states that an independent internal audit of portions of the EMS program will be performed each year. The internal audit of the 2014 EMS, was conducted in November and identified two procedural non-compliance issues, which were immediately corrected, and one opportunity for improvement. These were entered into caWeb for tracking and were resolved and closed in 2014.

Additionally, NSTec's Occupational Safety and Health Division conducts internal management assessments and compliance evaluations on focused portions of the EMS program. These assessments and evaluations determine the extent of compliance with environmental regulations and identify areas for overall improvement. In 2014, NSTec conducted a total of 7 internal management assessments and 74 compliance evaluations.

3.8 EMS Effectiveness and Reporting

The ISO 14001:2004 certification of the EMS program has enabled NNSA/NFO to declare that they have met executive and DOE order requirements. The ISO 14001:2004 certifying organization stated after the April 2014 recertification assessment that the EMS program remains effective, and the EMS program's certification was renewed in June 2014 for another 3 years.

EMS training and awareness has improved the overall environmental knowledge of the workforce. Many times the operational workers in the company identify problems and recommend preventive or corrective actions. These actions, driven by the EMS program, have improved performance and reduced costs.

The establishment of annual environmental EMS targets assists in reducing water, fuel, and energy usage; avoiding waste production; recycling wastes generated from environmental restoration activities; purchasing EPP products; and making infrastructure improvements on environmental systems such as water lines and boilers.

One of the benefits of the EMS program is monthly communication between NSTec and NNSA/NFO regarding current environmental issues and the status of EMS objectives and targets. NSTec prepares and distributes by email a monthly EMS slide presentation to facilitate communication and support, and topics include assessment findings, status of corrective actions, emerging concerns, environmental metrics, and opportunities for improvement. The EMS program is continuously being evaluated and improvements are implemented and documented. A summary report is presented to senior management annually, documenting performance and improvements, documenting the determination that the program continues to be suitable, adequate and effective.

On December 4, 2014, the 2014 Facility EMS Annual Report Data for the NNSS was entered into the DOE Headquarters EMS database accessed through the FedCenter.gov website (<http://www.fedcenter.gov/programs/ems/>). This database gathers information in several EMS areas from all DOE sites to produce a combined report reflecting DOE's overall performance compared to other federal agencies. The report includes a scorecard section, which is a series of questions regarding a site's EMS effectiveness in meeting the objectives of federal EMS directives. The NNSS scored "green," the highest score.

3.9 Awards and Recognition

2014 Federal Energy and Water Management Award – In 2014, the NNSS earned the 2014 Federal Energy and Water Management Award for NNSA/NFO's Alternative Fuel Vehicle (AFV) Management Program. The NNSS was the only DOE recipient of this distinguished award in 2014. The NNSS was recognized for deploying cutting-edge practices that will significantly cut carbon pollution while protecting the NNSS's environment. The award ceremony was held by the DOE Federal Energy Management Program (FEMP) at the National Archives in Washington, D.C. on December 2, 2014, where all FEMP award recipients were recognized. FEMP provides agencies with the information, tools, and assistance they need to meet and track their energy-related requirements

and goals, and honors agencies for saving energy and water in federal facilities. NNSA/NFO's AFV Management Program was responsible for increasing the use of renewable fuels on the NNSS in by 195% in FY 2013 and by 164% in FY 2014 when compared to the FY 2005 baseline. This increase was achieved through the construction of two ethanol (E-85) alternative fuel capable service stations and implementing an innovative fuel lock-out program that identifies flex fuel vehicles and prioritizes the use of E-85. This lockout program is a modification to the fuel management system that involved reprogramming the system to prevent AFVs from pumping non-renewable fuel at the service stations. The reprogramming was accomplished by the Fleet, Fuel, and Equipment Service Renewable Fuel Program Team. This significant increase in renewable fuel use on the NNSS effectively supports the national objective to reduce dependence on foreign oil.

2014 NNSA Environmental Stewardship Award – NNSS received one of the fifteen 2014 Environmental Stewardship awards presented by the NNSA to select national laboratories and sites to recognize their innovation and excellence in advancing sustainability objectives. The award was in the Green Buildings Category for work done to reduce energy use at Warehouse 23-160, the main warehouse in Mercury. In FY 2009, as part of an ESPC, lighting and heating controls were installed in the warehouse and resulted in significant power savings (37%) the following year. In FY 2013, a Clean Burn System was installed at the warehouse; four Clean Burn furnaces and four very large high-volume low-speed fans were installed. The Clean Burn System is a renewable energy source which utilizes recycled oil. One gallon of recycled oil generates the same amount of energy as 18 kilowatt hours of electricity. It takes about 8,000 gallons of recycled oil to heat the 50,000-square-foot warehouse for one winter. The oil currently being used by the Clean Burn System is generated through NSTec's Fleet, Fuel, and Equipment Preventative Maintenance Program. The energy cost savings to heat the warehouse will be approximately \$58,000 a year. Other improvements made to Warehouse 23-160 included:

- Installation of four high-speed, low-velocity fans.
- Installation of a water fountain with filter and meter. To date they have saved 1,744 bottles from going to the landfill. Water is still ordered but only for workers going out in the field.
- Replacement of high sodium 100 and 500 watt bulbs with 60 watt light emitting diode (LED) bulbs on the exterior of building (total of 8 lights).
- Replacement of 66 (32 watt) fluorescent bulbs with 15 watt LED bulbs.
- Installation of air strip curtains on two exterior rolling door exits.
- Sealing off roof vents inside the building with clear plexiglass. This prevents heating and cooling escaping through the vents and provides some day lighting in warehouse.
- Replacement of 40-gallon water heater with a 10-gallon water heater. The water heater services only the men's restroom.
- Placement of weather stripping around all walk-in entrance doors.

2014 DOE Sustainability Award – In February 2015, it was announced that NNSS was selected to receive a 2014 DOE Sustainability Award. This award is one of several new awards specifically selected by DOE's Sustainability Project Office staff to recognize outstanding sustainability commitment. It was awarded to recognize NNSS's noteworthy progress in effective energy, water, and vehicle fleet management, resulting in meeting many sustainability goals ahead of schedule (see Table 3-1). The NNSS has a commitment to meeting goals which could extend to 2020. NNSS's commitment to planning, reporting, and achieving DOE's sustainability goals are essential to ensuring DOE is a government-wide leader in sustainability.

National Security Technologies, LLC

Charles B. Davis

EnviroStat

Section 4.1 of this chapter presents the results of radiological air monitoring conducted on the Nevada National Security Site (NNSS) by the U.S. Department of Energy, National Nuclear Security Administration Nevada Field Office (NNSA/NFO) to verify compliance with radioactive air emission standards. Measurements of radioactivity in air are also used to assess the radiological dose to the general public from inhalation. The assessed dose to the public from all exposure pathways is presented in Chapter 9. Section 4.2 presents the results of nonradiological air quality assessments that are conducted to ensure compliance with NNSS air quality permits.

NNSA/NFO has also established an independent Community Environmental Monitoring Program to monitor radionuclides in air in communities adjacent to the NNSS. It is managed by the University of Nevada's Desert Research Institute (DRI) of the Nevada System of Higher Education. DRI's offsite air monitoring results are presented in Chapter 7.

4.1 Radiological Air Monitoring

The sources of radioactive air emissions on the NNSS include the following: (1) evaporation of tritiated water from containment ponds; (2) diffusion of tritiated water vapor from soil at the Area 3 Radioactive Waste Management Site (RWMS), the Area 5 Radioactive Waste Management Complex (RWMC), and historical surface or near-surface nuclear device test locations (particularly Sedan and Schooner Craters); (3) resuspension of contaminated soil at historical surface or near-surface nuclear device test locations; and (4) release of radionuclides from current operations. Figure 4-1 shows the location of all known historical and 2014 radiological air emission sources. Areas of soil contamination related to historical weapon tests are depicted in Figure 4-1 as "Grouped Area Sources". The NNSS air monitoring network consists of samplers placed near sites of soil contamination, at facilities that may produce radioactive air emissions, and along the NNSS boundaries. The objectives and design of the network are described in the *Routine Radiological Environmental Monitoring Plan* (Bechtel Nevada 2003).

Data from NNSS sampling stations are analyzed to meet the specific goals listed below. The analytes monitored include radionuclides most likely to be present in air as a result of past or current NNSS operations, based on inventories of radionuclides in surface soil (McArthur 1991) and on the volatility and availability of radionuclides for resuspension (see Table 1-5 in Chapter 1 for the half-lives of these radionuclides). Uranium is included because depleted uranium (DU) either has been, or currently is, used during exercises in specific areas of the NNSS. Samples from stations near these areas are analyzed for uranium. Gross alpha and gross beta readings are used in air monitoring as a relatively rapid screening measure.

<i>Radiological Air Monitoring Goals</i>	<i>Analytes Monitored</i>
<p>Monitor air at or near historical or current operation sites to (1) detect and identify local and site-wide trends, (2) quantify radionuclides emitted to air, and (3) detect accidental and unplanned releases.</p> <p>Conduct point-source operational monitoring required under NESHAP for any facility that has the potential to emit radionuclides to the air and cause a dose greater than 0.1 millirem per year (mrem/yr) (0.1 millisievert per year [mSv/yr]) to any member of the public.</p> <p>Determine if the air pathway dose to the public from past or current NNSS activities complies with the Clean Air Act (CAA) National Emission Standards for Hazardous Air Pollutants (NESHAP) standard of 10 mrem/yr (0.1 mSv/yr) (see Chapter 9).</p> <p>Determine if the total radiation dose to the public from all pathways (air, water, food) complies with the 100 mrem/yr standard set by U.S. Department of Energy (DOE) Order DOE O 458.1, "Radiation Protection of the Public and the Environment" (see Chapter 9).</p>	<p>Americium-241 (^{241}Am)</p> <p>Gamma ray emitters (includes Cesium-137 [^{137}Cs])</p> <p>Tritium (^3H)</p> <p>Plutonium-238 (^{238}Pu)</p> <p>Plutonium-239+240 ($^{239+240}\text{Pu}$)</p> <p>Uranium-233+234 ($^{233+234}\text{U}$)</p> <p>Uranium-235+236 ($^{235+236}\text{U}$)</p> <p>Uranium-238 (^{238}U)</p> <p>Gross alpha radioactivity</p> <p>Gross beta radioactivity</p>

Figure 4-1. Sources of radioluclide air emissions on the NNSS in 2014

4.1.1 Monitoring System Design

Environmental Samplers – A total of 18 environmental sampling stations operated on the NNSS at some time during 2014 (Figure 4-2). Of these 18 stations, 15 have both air particulate and tritium (atmospheric moisture) samplers, 1 has only an air particulate sampler, and 2 have only a tritium sampler (Figure 4-2). The NNSS air samplers are positioned in predominant downwind directions from sources of radionuclide air emissions and/or are positioned between NNSS contaminated locations and potential offsite receptors. (Wind rose data, showing predominant wind directions on the NNSS, are presented in Section A.3 of *Attachment A: Site Description*, which is included as a separate file on the compact disc of this report). Most radionuclide air emission sources are diffuse sources that include areas with (1) radioactivity in surface soil that can be resuspended by the wind, (2) tritium in water (tritiated water) transpiring or evaporating from plants and soil at the sites of past nuclear tests, and (3) tritiated water evaporating from ponds receiving water either from contaminated wells or from tunnels that cannot be sealed. Sampling and analysis of air particulates and tritium were performed at these stations as described in Section 4.1.2. Radionuclide concentrations measured at these stations are used for trending, determining ambient background concentrations in the environment, and monitoring for unplanned releases of radioactivity.

Critical Receptor Samplers – Six of the environmental sampling locations that have both air particulate and tritium samplers are approved by the U.S. Environmental Protection Agency (EPA) Region IX as critical receptor samplers. They are located near the boundaries and center of the NNSS (Figure 4-2). Radionuclide concentrations measured at these stations are used to assess compliance with the NESHAP public dose limit of 10 mrem/yr (0.1 mSv/yr). The annual average concentrations from each station are compared with the NESHAP Concentration Levels for Environmental Compliance (compliance levels [CLs]) listed in Table 4-1. Compliance with NESHAP is demonstrated when the sum of the fractions, determined by dividing each radionuclide's concentration by its CL and then adding the fractions together, is less than 1.0 at all stations.

Table 4-1. Regulatory concentration limits for radionuclides in air

Radionuclide	Concentration ($\times 10^{-15}$ microcuries/milliliter [$\mu\text{Ci/mL}$])	
	NESHAP Concentration Level for Environmental Compliance (CL) ^(a)	10% of Derived Concentration Standard (DCS) ^(b)
²⁴¹ Am	1.9	4.1
¹³⁷ Cs	19	9,800
³ H	1,500,000	1,400,000
²³⁸ Pu	2.1	3.7
²³⁹ Pu	2	3.4
²³³ U	7.1	39
²³⁴ U	7.7	40
²³⁵ U	7.1	45
²³⁶ U	7.7	44
²³⁸ U	8.3	47

(a) From Table 2, Appendix E of Title 40 Code of Federal Regulations (CFR) Part 61, 2010

(b) From DOE-STD-1196-2011, "Derived Concentration Technical Standard"

In addition to CLs, air concentrations measured at all locations are also compared with Derived Concentration Standard (DCS) values. They represent the annual average air concentrations that would result in a total effective dose equivalent (TEDE) (see Glossary, Appendix B) of 100 mrem/yr (the federal dose limit to the public from all radiological exposure pathways). Ten percent of the DCS (third column of Table 4-1) represents a 10 mrem/yr dose and is analogous to the CLs. Differences between the CL and 10% of the DCS are due to the fact that they are computed using different dose models. Generally, the more conservative of the two are the CLs used to demonstrate compliance. Air concentrations approaching 10% of the CLs are investigated for causes that may be mitigated in order to ensure that regulatory dose limits are not exceeded.

Point-Source (Stack) Sampler – Stack monitoring has been conducted in the past at one facility on the NNSS, the Joint Actinide Shock Physics Experimental Research (JASPER) facility in Area 27 (Figure 4-2). During 2013, the potential air emissions from the facility were re-evaluated and determined to result in a potential dose that is much less than the 0.1 mrem/yr threshold at which stack monitoring is required under NESHAP. The last air sample from

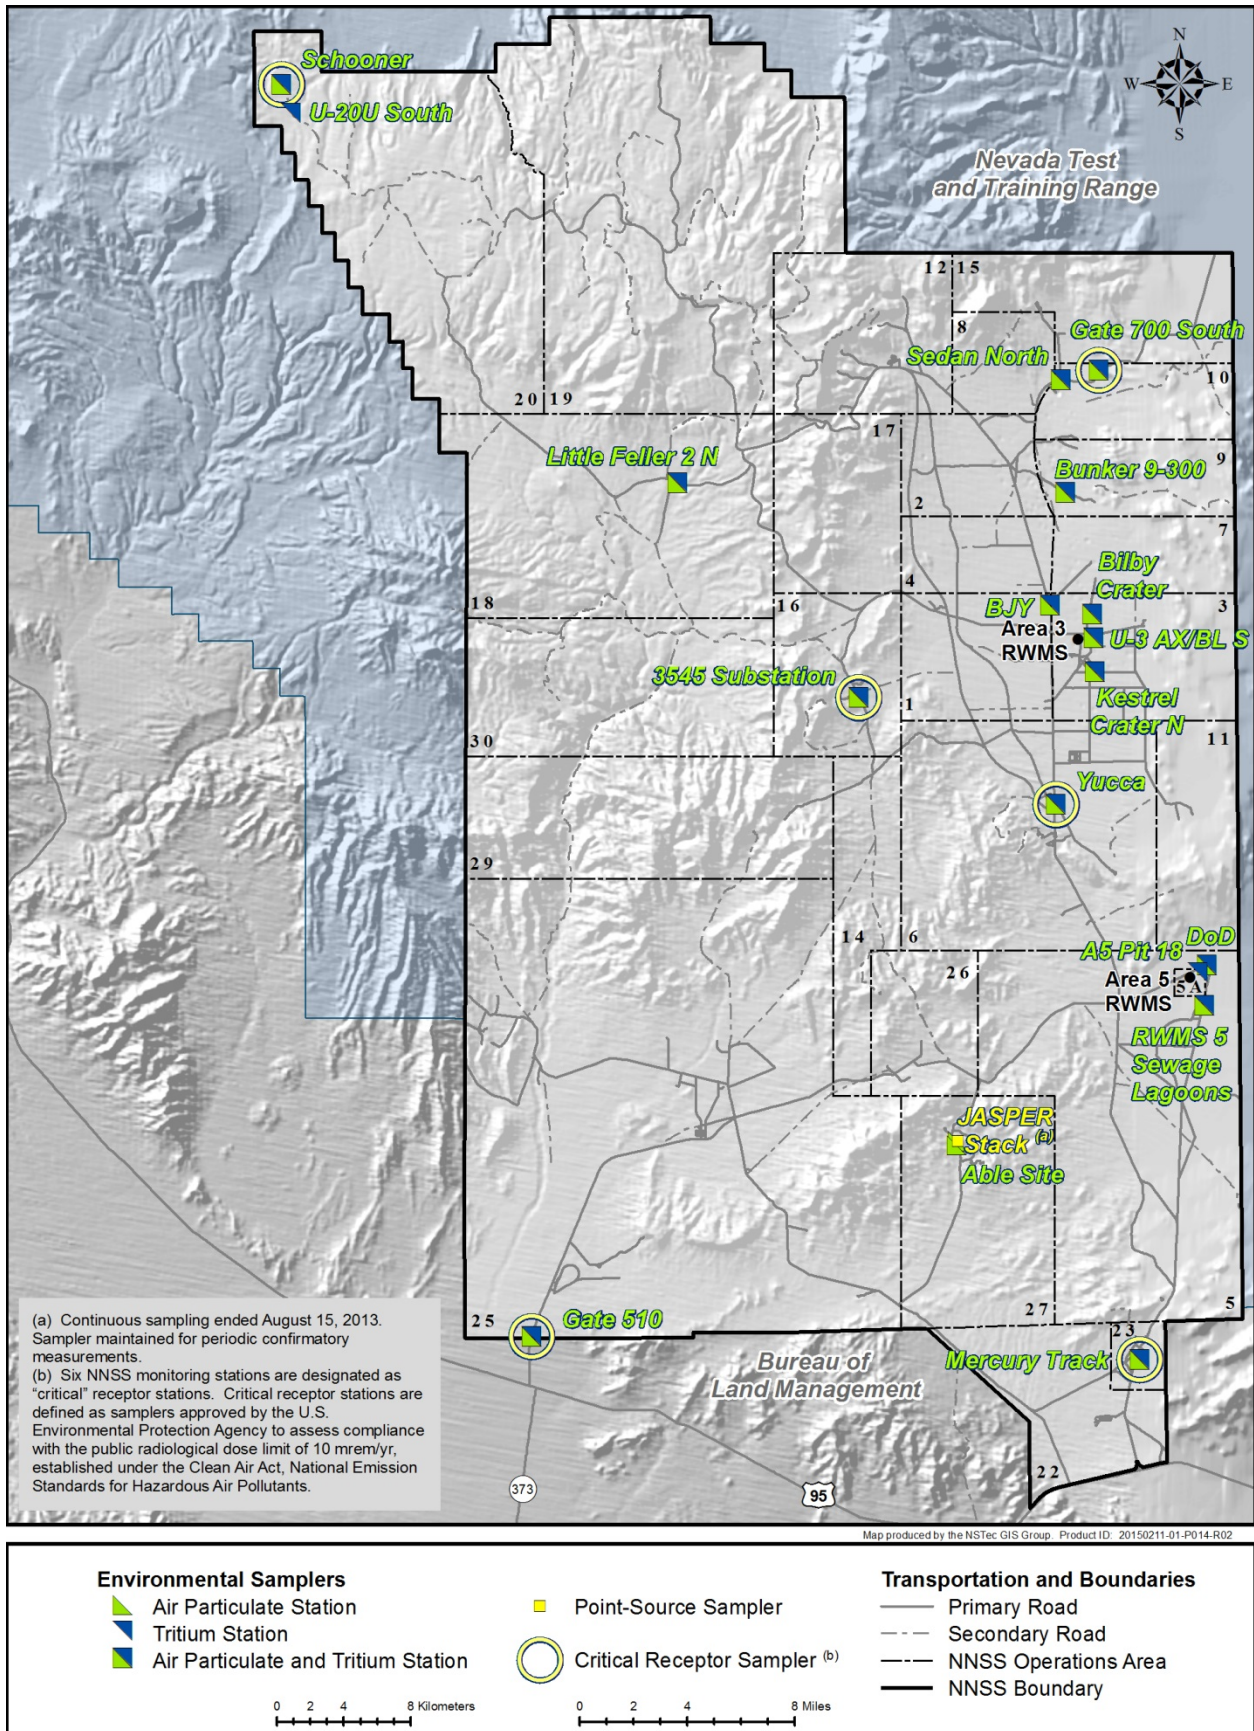

Figure 4-2. Radiological air sampling network on the NNSS in 2014

JASPER was collected August 15, 2013. Although continuous air monitoring was halted, the sampler is maintained in order to conduct periodic confirmatory measurements. No samples were collected at JASPER in 2014.

4.1.2 Air Particulate and Tritium Sampling Methods

A sample is collected from each air particulate sampler by drawing air through a 10-centimeter (cm) (4-inch [in.]) diameter glass-fiber filter at a flow rate of about 85 liters (3 cubic feet [ft³]) per minute. The particulate filter is mounted in a filter holder that faces downward at a height of 1.5 meters (m) (5 feet [ft]) above ground. A timer measures the operating time. The run time multiplied by the flow rate yields the volume of air sampled, which is about 1,720 cubic meters (m³) (60,000 ft³) during a typical 14-day sampling period. The air sampling rates are measured using mass-flow meters that are calibrated annually. The filters are collected every 2 weeks.

The filters are analyzed for gross alpha and gross beta radioactivity after a 5-day holding time to allow for the decay of naturally occurring radon progeny. These filters are then composited quarterly for each station. The composite samples are analyzed for gamma-emitting radionuclides (including ¹³⁷Cs) by gamma spectroscopy and for ²³⁸Pu, ²³⁹⁺²⁴⁰Pu, and ²⁴¹Am by alpha spectroscopy after chemical separation. Samples from stations relatively near potential sources of uranium emissions are also analyzed for uranium isotopes by alpha spectroscopy. These stations are RWMS 5 Lagoons (Area 5), Yucca (Area 6), Gate 700 S (Area 10), 3545 Substation (Area 16), Gate 510 (Area 25), and Able Site (Area 27). In the past, filters had been collected weekly and composited monthly. The current monthly/quarterly schedule was instituted in the second quarter of 2012 in Areas 3 and 5 and in the first quarter of 2014 for all other Areas. This extended schedule is intended to increase the volume of air sampled and thereby increase the amount of radioactivity that would be deposited on the filters and enhance the ability to measure lower concentrations.

Tritiated water vapor in the form of ³H³HO or ³HHO (collectively referred to as HTO) is sampled continuously at each tritium sampling station. Tritium samplers are operated with elapsed time meters at a flow rate of about 566 cubic centimeters per minute (1.2 ft³ per hour). The total volume sampled is determined from the product of the sampling period and the flow rate (about 11 m³ [388 ft³] over a 2-week sampling period). The HTO is removed from the airstream by a molecular sieve desiccant which is exchanged biweekly. An aliquot of the total moisture collected is extracted from the desiccant and analyzed for tritium by liquid scintillation counting. In all cases, measured activity in units per sample is converted to units per volume of air prior to reporting in the following sections.

Quality control air samples (e.g., duplicates, blanks, and spikes) are also routinely incorporated into the analytical suites. Chapter 16 contains a discussion of quality assurance/quality control protocols and procedures used for radiological air monitoring.

4.1.3 Presentation of Air Sampling Data

The 2014 annual average radionuclide concentrations at each air sampling station are presented in the following sections. The annual average concentration for each radionuclide is estimated from uncensored analytical results for individual samples; i.e., values less than their analysis-specific minimum detectable concentrations (MDCs) (see Glossary, Appendix B) are included in the calculation. ²³⁹⁺²⁴⁰Pu, ²³³⁺²³⁴U, and ²³⁵⁺²³⁶U are reported as the sum of isotope concentrations because the analytical method cannot readily distinguish the individual isotopes. Where field duplicate measurements are available, plots and summaries use the average of the regular and field duplicate measurements.

In graphs of concentration data in the following figures, the CL (second column of Table 4-1) or a fraction of the CL is included as a dashed green horizontal line. For graphs displaying individual measurements, the CL or fraction thereof is shown for reference only, because assessment of NESHAP compliance is based on annual average concentrations rather than individual measurements.

4.1.4 Air Sampling Results

Radionuclide concentrations in the air samples shown in the following tables and graphs are attributed to the resuspension of legacy contamination in surface soils and to the upward flux of tritium from the soil at sites of past nuclear tests and buried low-level radioactive waste.

4.1.4.1 Americium-241

The mean ^{241}Am concentration for environmental sampler stations is $8.55 \times 10^{-18} \mu\text{Ci/mL}$. This is not a significant change from recent years, as it is slightly lower than 2013 ($10.09 \times 10^{-18} \mu\text{Ci/mL}$), 2012 ($12.74 \times 10^{-18} \mu\text{Ci/mL}$), and 2011 ($15.99 \times 10^{-18} \mu\text{Ci/mL}$) but somewhat higher than 2010 ($6.99 \times 10^{-18} \mu\text{Ci/mL}$) and 2009 ($6.33 \times 10^{-18} \mu\text{Ci/mL}$). The 2014 average concentration is less than 0.5% of the CL. As usual, the highest concentrations are detected at the Bunker 9-300 sampling station in Area 9 (Table 4-2, Figure 4-3). This sampler is located within areas of known soil contamination from past nuclear tests. The annual mean concentration at Bunker 9-300 is $81.32 \times 10^{-18} \mu\text{Ci/mL}$, 4.3% of the CL (shown at bottom of Table 4-2). In Figures 4-3 through 4-5, the measurements at Bunker 9-300 are shown individually. The plots also show the mean of quarterly concentrations at other stations, with vertical bars extending from the lowest to highest measurements at the other stations.

Table 4-2. Concentrations of ^{241}Am in air samples collected in 2014

4.1.4.2 Cesium-137

During 2014, ^{137}Cs was detected at levels slightly above their MDCs in only three samples. These were all in third quarter composite samples collected from the Sedan N, Bunker 9-300, and ABLE Site stations. Sedan N and Bunker 9-300 are located within, or very near, areas of known soil contamination from past nuclear tests. All measured concentrations were very low (Table 4-3, Figure 4-4). The highest single sample measurement (at Sedan N) was 1.5% of the CL; the highest annual mean (also at Sedan N) was 0.5% of the CL.

(a) EPA-approved Critical Receptor Station

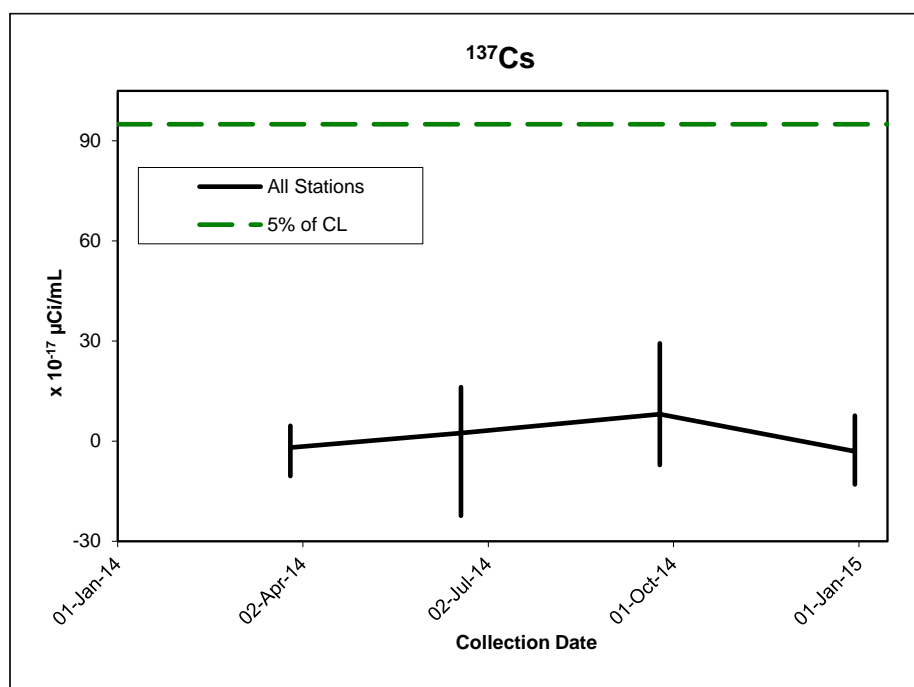

Figure 4-4. Concentrations of ^{137}Cs in air samples collected in 2014

4.1.4.3 Plutonium Isotopes

The overall mean concentration for ^{238}Pu at environmental stations in 2014 (2.30×10^{-18} $\mu\text{Ci/mL}$) is within the range of values (1.15 to 3.72×10^{-18} $\mu\text{Ci/mL}$) observed since 2009. Average Bunker 9-300 measurements are again higher than those of other stations (Table 4-4, Figure 4-5), although less prominently so in comparison with ^{241}Am (Figure 4-3) and $^{239+240}\text{Pu}$ (Figure 4-6). The highest mean concentration at environmental stations is 0.5% of the CL.

The $^{239+240}\text{Pu}$ isotopes are of greater abundance and hence greater interest. The overall mean of 55.8×10^{-18} $\mu\text{Ci/mL}$ in 2014 (Table 4-5) is within the range of values measured over the past 8 years. The location with the highest mean, as expected, is Bunker 9-300 (549×10^{-18} $\mu\text{Ci/mL}$, 27.4% of the CL; Table 4-4 and Figure 4-6). The higher plutonium values at this station are primarily due to diffuse sources of radionuclides from historical nuclear testing in Area 9.

The temporal patterns for ^{241}Am , $^{239+240}\text{Pu}$, and to some extent ^{238}Pu at Bunker 9-300, shown in Figures 4-3, 4-6, and 4-5, respectively, are correlated. This is because ^{241}Am is the long-lived daughter product obtained when ^{241}Pu (a short-lived isotope created along with the more common Pu isotopes) decays by beta emission. Hence, $^{239+240}\text{Pu}$ and ^{241}Am (and also ^{238}Pu to some extent) tend to be found together in particles of Pu remaining from past nuclear tests. The half-life of ^{241}Pu is 14.4 years, whereas that of ^{241}Am is 432 years. Consequently, the amount of ^{241}Am will gradually increase as ^{241}Pu decays; then it will decrease by half every 432 years.

Figure 4-7 shows long-term trends in $^{239+240}\text{Pu}$ annual mean concentrations at locations with at least 15-year data histories since 1970. Rather than showing the time histories for all 47 locations, Figure 4-7 shows the average (geometric mean) trend lines for Areas 1 and 3; Area 5; Areas 7, 9, 10, and 15; and the other areas. Areas 1, 3, 7, 9, 10, and 15, in the northeast portion of the NNSS, have a legacy of soil contamination from surface and atmospheric nuclear tests and safety shots. The average annual rates of decline for these groups range from 2.2% (Areas 1 and 3) and 2.9% (Areas 7, 9, 10, and 15) to over 12% (“Other Areas” group). This equates to an environmental half-life for $^{239+240}\text{Pu}$ in air of 30.6 years for Areas 1 and 3; 20.8 years for Areas 7, 9, 10, and 15; 7.2 years for Area 5; and 5.2 years for the “Other Areas” group. Declining rates are not attributed to radioactive decay, as the physical half-lives of ^{239}Pu and ^{240}Pu are 24,110 and 6,537 years, respectively. The decreases are due primarily to immobilization and dilution of Pu particles in soil, resulting in reduced concentrations suspended in air. The half-life of the less abundant ^{238}Pu is 88 years.

Table 4-4. Concentrations of ^{238}Pu in air samples collected in 2014

4.1.4.4 Uranium Isotopes

Uranium analyses were performed in 2014 for samples from six stations located relatively near sites where exercises using uranium (predominately DU) have been conducted. Concentrations of uranium detected in samples were not above background levels and isotopic ratios indicate these are natural uranium. Therefore, it is concluded that negligible amounts of man-made uranium were present in NNSS samples during 2014.

4.1.4.5 Tritium

Measurements of tritium in air vary widely across monitoring stations on the NNSS (Table 4-6). The highest mean concentration was detected at the Schooner station (130×10^{-6} picocuries per milliliter [pCi/mL]). The next highest are 3.2×10^{-6} pCi/mL at RWMS 5 Lagoons, 2.4×10^{-6} pCi/mL at Sedan N, and 1.8×10^{-6} pCi/mL at DoD. Figure 4-8 shows these data with the Schooner data plotted at one-tenth of their actual values to allow the variation at other locations to be visible. The Schooner annual mean is 8.7% of the CL; mean concentrations at other locations are less than 0.2% of the CL.

The tritium found at Schooner and Sedan N comes from past nuclear tests. Tritium associated with these tests quickly oxidizes into tritiated water, which remains in the surrounding soil and rubble until it moves to the surface and evaporates. Higher tritium concentrations in air are generally observed during the summer months. Increased tritium emissions are likely due to the movement of relatively deep soil moisture (> 2 m), containing relatively high concentrations of tritium, to the surface when temperatures are the highest and when shallow (< 2 m) soil moisture is the lowest. Rainfall can temporarily suppress these emissions by diluting tritium in the atmosphere and in the shallow soil moisture. Figure 4-8 shows the relationship between tritium and average daily temperature at Schooner Crater. Figure 4-9 shows the amount of precipitation occurring during monitoring periods in and around Pahute Mesa; note the dip in tritium emissions following the rains of mid-July and early September.

Figure 4-10 shows average (geometric mean) long-term trends for the annual mean tritium levels at locations with at least 7-year histories since 1989. Tritium measurements have been decreasing fairly rapidly at most locations; the overall average decline rate for stations other than Schooner is around 16% per year. The decline rate for Schooner has been about 10% per year since 2002.

4.1.4.6 Gross Alpha and Gross Beta

The gross alpha and gross beta radioactivity in air samples collected in 2014 are summarized in Tables 4-7 and 4-8. Because these radioactivity measurements include naturally occurring radionuclides (such as potassium-40, beryllium-7, uranium, thorium, and the daughter isotopes of uranium and thorium) in uncertain proportions, a meaningful CL cannot be constructed. These analyses are useful in that results can be economically obtained just 5 days after sample collection to identify any increases requiring investigation.

Overall, the distribution of mean gross alpha results across the network is comparable with those of the past few years. The gross beta measurements also resemble those of prior years, excluding the briefly elevated values in March 2011 due to the Fukushima Daiichi nuclear power plant event. The mean gross beta values are similar, and there are no stations with data that stand out from the rest.

(a) EPA-approved Critical Receptor Station

4.1.5 2014 Air Sampling Results from Critical Receptor Samplers

The following radionuclides from NNSS-related activities were detected at one or more of the critical receptor samplers: ^{241}Am , ^{238}Pu , $^{239+240}\text{Pu}$, and ^3H . All of their measured concentrations were well below their CLs. No man-made uranium was detected above background levels (see Section 4.1.4.4). The concentration of each measured man-made radionuclide at each of the six critical receptor stations is divided by its respective CL (see Table 4-1) to obtain a “percent of CL.” These are then summed for each station. The sum of these fractions at each critical receptor sampler is far less than 1, demonstrating that the NESHAP dose limit (10 mrem/yr) at these critical receptor locations was not exceeded (Table 4-9). The highest radiation TEDE (see Glossary, Appendix B) at a critical receptor location would be approximately 0.90 mrem from air to a hypothetical individual residing at Schooner for the entire calendar year. A more realistic estimate of dose to the offsite public would come from using the 0.002 sum of fractions from the Gate 510 sampler, which is closest to the nearest public receptor (about 3.5 kilometers [km] or 2.2 miles (mi)). The estimated TEDE from air emissions for a hypothetical individual living year-round at the Gate 510 sampler would be 0.02 mrem/yr.

Table 4-9. Sum of fractions of compliance levels for man-made radionuclides at critical receptor samplers

Radionuclides Included in Sum of Fractions	NNSS Area	Sampling Station	Sum of Fractions of Compliance Levels (CLs)

	10	Gate 700 S	0.008
	16	3545 Substation	0.002
	20	Schooner	0.090
	23	Mercury Track	0.002
	25	Gate 510	0.002

4.1.6 Emission Evaluations for Planned Projects

During 2014, two NESHAP evaluations were conducted. The first was to estimate a worst case dose resulting from the resuspension of radiologically contaminated soil during the planned detonation of unexploded ordnance (for disposal purposes) near Buggy, a Project Plowshare site (see Chapter 1, Section 1.3) in Area 30. The second evaluation was in support of the planned Noble Gas Migration Experiment at the existing drill hole U20az in Area 20. Gas samples, collected from the drill hole, were to be transported to an offsite facility and analyzed for a non-radioactive tracer gas. Because the samples may contain radioactive noble gases, a NESHAP evaluation was done to estimate the offsite dose to the public from potential emissions.

Both evaluations were conducted to determine if the projects had the potential to release airborne radionuclides that would expose the public to a dose equal to or greater than 0.1 mrem/yr. For any project or facility with this potential, the EPA requires approval prior to operation and point-source operational monitoring. The predicted dose at the nearest NNSS boundary for each planned project was much less than the 0.1 mrem/yr level specified in 40 CFR 61.96. Therefore, it was concluded that these activities constituted minor sources and did not require point-source operational monitoring. The detailed air emission dose evaluations for each project are reported in the NESHAP annual report for 2014 (National Security Technologies, LLC [NSTec], 2015).

4.1.7 Unplanned Releases

There were no known unplanned radionuclide releases in 2014. There were no documented wildland fires in radiologically contaminated areas, or in any other areas on the NNSS in 2014.

4.1.8 Estimate of Total NNSS Radiological Atmospheric Releases in 2014

Each year, existing operations, new construction projects, and modifications to existing facilities that have the potential for airborne emissions of radioactive materials are reviewed. Quantities of radionuclides released during these operations and from legacy contamination sites are measured or calculated to obtain the total annual quantity of radiological atmospheric releases from the NNSS. The methods used are described in detail in NSTec (2015). The 2014 emission sources are presented in Table 4-10. Their locations in relation to critical receptor air monitoring locations are shown in Figure 4-1.

A number of other short-lived radionuclides were released in 2014 at the Tumbleweed Test Range and the T1 Training and Exercise Area: beryllium-7 (^7Be), carbon-11 (^{11}C), nitrogen-13 (^{13}N), oxygen-15 (^{15}O), chlorine-38 (^{38}Cl), chlorine-39 (^{39}Cl), argon-41 (^{41}Ar), and metastable technetium-99 ($^{99\text{m}}\text{Tc}$). All but ^7Be have half-lives ranging from 10 minutes (^{13}N) to 6 hours ($^{99\text{m}}\text{Tc}$). They decay away very quickly and are not available to contribute dose to the public at the 31 to 62 km (19 to 38 mi) distances over which they have to travel. ^7Be has a 54-day half-life but is emitted in quantities much lower than the concentrations of ^7Be produced in the atmosphere by naturally occurring cosmic radiation.

In 2014, an estimated 5,804 Ci of radionuclides were released as air emissions. Of this amount, 85% (4,926 Ci) is from activation products with very short half-lives discussed above; 878 Ci (15%) were tritium (Table 4-11). Descriptions of the methods used for estimating the quantities shown in Table 4-10 are reported in NSTec (2015).

4.1.9 Environmental Impact

The concentrations of man-made radionuclides in air on the NNSS are all less than the regulatory concentration limits specified by federal regulations. Also, air monitoring data at the six critical receptor samplers indicate that the radiological dose to the general public from the air pathway is below the NESHAP standard of 10 mrem/yr (see Chapter 9 for a discussion of dose to the public from all pathways). Nearly all radionuclides detected by environmental air samplers in 2014 appear to be from two sources: (1) legacy deposits of radioactivity on and in the soil from past nuclear tests, and (2) the upward flux of tritium from the soil at sites of past nuclear tests and low-level radioactive waste burial. Long-term trends of ²³⁹⁺²⁴⁰Pu and tritium in air continue to show a decline with time. Radionuclide concentrations in plants and animals on the NNSS and their potential impact are discussed in Chapter 8.

4.2 Nonradiological Air Quality Assessment

NNSS operations that are potential sources of air pollution include aggregate production, surface disturbance (e.g., construction), release of fugitive dust from driving on unpaved roads, use of fuel-burning equipment, open burning, venting from bulk fuel storage facilities, explosives detonations, and releases of various chemicals during testing. Air quality assessments are conducted to document compliance with the current State of Nevada air quality permit that regulates specific operations or facilities on the NNSS. The assessments mainly address nonradiological air pollutants. The State of Nevada has adopted the CAA standards, which include NESHAP, National Ambient Air Quality Standards (NAAQS), and New Source Performance Standards (NSPS) (see Section 2.2). NESHAP compliance with radionuclide emissions monitoring and with the air pathway public dose limits are presented in Section 4.1 of this chapter. Compliance with all other CAA air quality standards is addressed in this section. Data collection, opacity readings, recordkeeping, and reporting activities on the NNSS are conducted to meet the specific program goals in the table below.

<i>Air Quality Assessment Program Goals</i>
Ensure that NNSS operations comply with all the requirements of the current air quality permit issued by the State of Nevada.
Ensure that emissions of criteria air pollutants (sulfur dioxide [SO ₂]), nitrogen oxides [NO _x], carbon monoxide [CO], volatile organic compounds [VOCs], and particulate matter) and emissions of hazardous air pollutants do not exceed limits established under NAAQS and NESHAP, respectively.
Ensure that emissions of permitted NNSS equipment meet the opacity criteria to comply with NAAQS and NSPS.
Ensure that NNSS operations comply with the asbestos abatement reporting requirements under NESHAP.
Document usage of ozone-depleting substances (ODS) to comply with Title VI of the CAA.

4.2.1 Permitted NNSS Facilities

NNSA/NFO maintains a Class II Air Quality Operating Permit (AP9711-2557) for NNSS activities. State of Nevada Class II permits are issued for sources of air pollutants considered “minor,” i.e., where annual emissions must not exceed 100 tons of any one criteria pollutant (see Glossary, Appendix B), 10 tons of any one hazardous air pollutant (HAP) (see Glossary, Appendix B), or 25 tons of any combination of HAPs. The NNSS facilities regulated by permit AP9711-2557 include the following:

- Approximately 14 facilities/131 pieces of equipment in Areas 1, 5, 6, 12, 23, 25, 26, 27, and 29
- Chemical Releases at the Nonproliferation Test and Evaluation Complex (NPTEC) in Area 5 and in Port Gaston in Area 26
- Site-Wide Chemical Releases (conducted throughout the NNSS)
- Big Explosives Experimental Facility (BEEF) in Area 4
- Explosives Ordnance Disposal Unit (EODU) in Area 11
- Explosives Activities Sites at NPTEC in Area 5; High Explosives Simulation Test (HEST) in Area 14; Test Cell C, Calico Hills, and Army Research Laboratory (ARL) in Area 25; Port Gaston in Area 26; and Baker in Area 27

4.2.2 Permit Maintenance Activities

A permit application to renew the NNSS air permit (AP9711-2557) was submitted to the Nevada Division of Environmental Protection (NDEP) in April 2014 prior to the permit’s expiration in June 2014. The new permit has not yet been issued, but because the application was submitted prior to the State’s deadline, operations at the

NNSS continue under a permit “shield.” Also, the PM10 (particulate matter equal to or less than 10 microns in diameter) Sampling and Meteorological Monitoring Systems Plan, required as part of permit renewal application, was reformatted to incorporate all facilities into a single plan. New operational allowances requested in the 2014 permit renewal application included:

- Elimination of the PM10 monitoring requirement for chemical releases (which do not contain particulates).
- Modification of the EODU reporting requirement to coincide with the submittal of other facility quarterly reports.
- Reduction of the site-wide HAP emissions cap for a single pollutant from 7 tons/year down to 1 ton/year. Actual emissions are typically < 1 ton/year, and this decrease would reduce annual fees by \$2,000.

Also, all operational allowances previously requested as modifications to the old permit were requested again as part of the renewal application. They included:

- Revision of the recordkeeping requirements for seven remotely located fuel-fired generators.
- Removal of the requirement to report the Community Environmental Monitoring Program offsite air monitoring results from the permit.
- Elimination of the performance emissions test (“stack test”) requirement for five diesel-fired generators and for eight baghouses associated with the aggregate plant, batch plant, and cementing services facilities.

4.2.3 Emissions of Criteria Air Pollutants and Hazardous Air Pollutants

A source’s regulatory status is determined by the maximum number of tons of criteria air pollutants and nonradiological HAPs it may emit in a 12-month period if it were operated for the maximum number of hours and at the maximum production amounts specified in the source’s air permit. This maximum emission quantity, known as the potential to emit (PTE), is specified in an Air Emissions Inventory of all emission units. Each year, NNSA/NFO submits Actual Production/Emissions Reporting Forms to NDEP as required by the NNSS air permit. These forms are used to report the operational information and the calculated emissions of the criteria air pollutants and HAPs for permitted emission units. The State uses the information to determine permit fees and to verify that emissions do not exceed the PTEs. Quarterly reports of emission quantities were submitted to NDEP in April, July, and October 2014, and January 2015. The Calendar Year 2014 Actual Production/ Emissions Reporting Form was submitted in February 2015.

In July 2014, an emergency generator in Area 6 turned on automatically and operated more than its allowed 100 hours per year during what was initially perceived as a non-emergency situation. The emergency generator was shut down, NDEP was notified, and an environmental occurrence report was prepared (see Chapter 2, Table 2-12). This resulted in a Notice of Alleged Violation that was issued by NDEP as a “warning.” All other records examined in 2014 for permitted facilities and equipment indicated that operational parameters were being properly tracked and no PTEs were exceeded. An estimated 9.53 tons of criteria air pollutants were released (Table 4-12). The majority of the emissions were NO_x from diesel generators. An estimated 0.03 tons of HAPs were released in 2014. Table 4-13 shows the calculated tons of air pollutants released on the NNSS over the past 10 years. Fluctuations in emissions over time reflect changes in project activities and in facility operations.

Field measurements of particulate matter equal to or less than 10 microns in diameter (PM10) are required for all permitted explosives activities. The sampling systems must operate and record ambient PM10 concentrations at least each day a detonation or chemical release occurs. The PM10 emissions are reported to the State in reports specific to each series of detonations or chemical releases.

Unless specifically exempted, the open burning of any combustible refuse, waste, garbage, or oil is prohibited. Open burning for other purposes is allowed if approved in advance by the State through issuance of an Open Burn Authorization prior to each burn. Open Burn Authorizations must be renewed annually. At the NNSS, they are issued for fire extinguisher training and for support-vehicle live-fire training activities. In 2014, 20 fire extinguisher training sessions and 45 vehicle burns were conducted at the NNSS. Some of the fire extinguisher sessions used a new system that burns propane rather than diesel fuel, resulting in greatly reduced hydrocarbon emissions. Quantities of criteria air pollutants produced by open burns are not required to be calculated or reported.

Table 4-12. Tons of criteria air pollutant emissions released on the NNSS from permitted facilities operational in 2014

Facility	Calculated Tons ^(a) per Year of Emissions

Hazardous Air Pollutants (HAPs) ^(c)	0.05	1.87	0.02	0.09	0.30	0.02	0.04	0.03	0.23 ^(d)	0.03 ^(d)

(a) For mtons, multiply tons by 0.9072

(b) Particulate matter equal to or less than 10 microns in diameter

(c) The site-wide PTE for HAPs is 8 tons per individual HAP and 23.3 tons for all HAPs combined

(d) Total HAPs came predominantly from chemical tests at NPTEC (0.0147 tons/yr)

4.2.4 Performance Emission Testing and State Inspection

The current NNSS air permit requires performance emission testing of equipment that vents emissions through stacks (called “point sources”). The tests must be conducted once during the 5-year life of the NNSS air permit for each specified source. Once a source accumulates 100 hours of operation (since issuance of the permit in June 2002), it must be tested within 90 days. Testing is conducted by inserting a probe into the stack while the equipment is operating. Visible emissions readings must also be conducted by a certified evaluator during the tests. No performance emission tests were conducted in 2014. No state air inspections were conducted in 2014. It is anticipated that once the renewed NNSS air permit is issued (see Section 4.2.2), none of the equipment will require performance testing.

4.2.5 Opacity Readings

Visual opacity readings are conducted in accordance with permit and regulatory requirements. Personnel that take opacity readings are certified semiannually. In 2014, six employees on the NNSS were certified. Readings were taken for the following NNSS facilities regulated under the NAAQS opacity limit of 20%: Area 1 Concrete Batch Plant, Area 1 Wet Aggregate Plant, Area 6 Storage Silos, and several diesel generators located in Area 23. Readings for these facilities ranged from 0 to 10%. None of the readings exceeded the 20% limit.

4.2.6 Chemical Releases and Detonations Reporting

The NNSS air permit regulates the release of chemicals at specific locations under three separate “systems”: NPTEC in Area 5 (System 29), Site-Wide Releases throughout the NNSS (System 81), and Port Gaston in Area 26 (System 95). The types and amounts of chemicals that may be released vary depending on the system. In 2014, the Tarantula IX chemical test series was conducted at the Area 5 NPTEC. For this series, numerous small chemical releases were conducted over a 10-day period. The majority of the chemicals released were non-regulated; only minimal quantities of VOCs were released (see Table 4-12). No permit limits were exceeded.

Near-surface explosives detonations can take place at nine locations on the NNSS (BEEF in Area 4; EODU in Area 11; NPTEC in Area 5; Port Gaston in Area 26; HEST in Area 14; Test Cell C, Calico Hills, and ARL in Area 25; and Baker in Area 27). BEEF is permitted to detonate large quantities of explosives (up to 41.5 tons per detonation with a limit of 50.0 tons per 12-month period), while the other locations are limited to much smaller quantities (1 ton per detonation with a limit of 10 tons per 12-month period). Permitted limits exist also for the amounts of criteria air pollutant and HAP emissions generated by the detonations. In 2014, explosives were detonated at BEEF and Port Gaston, and no permit limits were exceeded (see Table 4-12).

PM10 monitoring was conducted for each chemical release test and detonation at NPTEC and Port Gaston in 2014. Monitoring was conducted in accordance with the permit and met calibration and performance audit requirements.

In addition to annual reporting, the NNSS air quality operating permit requires the submittal of test plans and final analysis reports to the State for detonations and chemical releases or release series. For BEEF, quarterly test plans and final reports must be submitted for the types and weights of explosives used and estimated emissions that may be released. Completion reports are submitted at the end of each calendar quarter for all chemical releases and detonations. In 2014, all of the required quarterly reports were submitted prior to the reporting deadline.

4.2.7 ODS Recordkeeping

At the NNSS, refrigerants containing ODS are mainly used in air conditioning units in vehicles, buildings, refrigerators, drinking water fountains, vending machines, and laboratory equipment. Halon 1211 and 1301, classified as ODS, have been used in the past in fire extinguishers and deluge systems, but all known occurrences of these halons have been removed from the NNSS. ODS recordkeeping requirements applicable to NNSS operations include maintaining evidence of technician certification for 3 years, recycling/recovery equipment approval, and servicing records for appliances containing 22.7 kilograms (50 pounds) or more of refrigerant.

4.2.8 Asbestos Abatement

A Notification of Demolition and Renovation Form is submitted to the EPA at least 10 working days prior to the start of a demolition or renovation project if the quantities of asbestos-containing material (ACM) to be removed are estimated to equal or exceed 260 linear feet, 160 square feet, or 1 m³. Small asbestos abatement projects are conducted throughout the year consisting of the removal of lesser quantities of ACM within a single facility per project, and a Notification of Demolition and Renovation Form is not required for these projects.

Seven Notification of Demolition and Renovation Forms were submitted during 2014. All of these were renovation projects conducted by subcontractors performing work in Area 25. Each project was performed in a closely supervised and rigidly controlled environment with personal air monitoring and/or environmental air sampling conducted by the subcontractor. The remaining asbestos abatement activities throughout the NNSS complex were minor in scope, involving the removal of quantities of ACM less than the reporting threshold per facility. ACM was buried in the Area 23 solid waste disposal site. Asbestos abatement records continued to be maintained as required.

The recordkeeping requirements for asbestos abatement activities include maintaining air and bulk sampling data records, abatement plans, and operations and maintenance activity records for up to 75 years, and maintaining location-specific records of ACM for a minimum of 75 years. Compliance is verified through periodic internal assessments.

4.2.9 Fugitive Dust Control

The NNSS Class II Air Quality Operating Permit states that the best practical methods should be used to prevent particulate matter from becoming airborne prior to the construction, repair, demolition, or use of unpaved or untreated areas. At the NNSS, the main method of dust control is the use of water sprays. In 2014, field personnel observed operations throughout the NNSS for the occurrence of excessive fugitive dust, and water sprays were used to control dust at sites where trenching and digging activities occurred in Areas 6 and 23.

Off the NNSS, all NNSA/NFO surface-disturbing activities that cover 5 or more acres are regulated by stand-alone Class II Surface Area Disturbance (SAD) permits issued by the State. Current SADs exist for the operation of three Underground Test Area (UGTA) wells on the Nevada Test and Training Range: ER-EC-13, ER-EC-14, and ER-EC-15. No excessive fugitive dust from these well sites was noted in 2014, and all requirements of the SADs were met.

4.2.10 Environmental Impact

During 2014, NNSS activities produced a total of 9.53 tons of criteria air pollutants and 0.03 tons of HAPs. These small quantities had little, if any, impact on air quality on or around the NNSS. NNSS air pollutant emissions are very low compared to the estimated daily releases from point sources in Clark County, Nevada. For example, the average annual projected emissions of NO_x in Clark County for base year 2002 through projected year 2018 is 37,549 tons per year compared to the estimated annual release from the NNSS in 2014 of 6.12 tons, 0.02% of Clark County's projected annual emissions of NO_x (Pollack 2007).

Impacts of the chemical release tests at the NNSS are minimized by controlling the amount and duration of each release. Biological monitoring at NPTEC is performed if there is a risk of significant exposure to downwind plants and animals from the planned tests. To date, chemical releases at NPTEC and other locations have used such small quantities (when dispersed into the air) that downwind test-specific monitoring has not been necessary. No measurable impacts to downwind plants or animals have been observed.

EnviroStat

This chapter presents the most recent results of water monitoring conducted by the U.S. Department of Energy, National Nuclear Security Administration Nevada Field Office (NNSA/NFO) on and adjacent to the Nevada National Security Site (NNSS). NNSA/NFO monitors groundwater to ensure that drinking water for NNSS workers and visitors is safe, that NNSS groundwater is protected from contamination from current activities, and to take corrective actions to protect the public and the environment from areas of known underground radiological contamination resulting from historical nuclear testing. Monitoring is conducted to comply with all applicable state and federal water quality and water protection regulations, U.S. Department of Energy (DOE) directives, and the Federal Facility Agreement and Consent Order (FFACO) between the U.S. Department of Energy, the U.S. Department of Defense, and the State of Nevada (see Section 2.3).

The Nevada State Health Division's Bureau of Health Care Quality and Compliance is allowed access to the NNSS to independently sample onsite water supply wells at its discretion. Monitoring results from the State's independent sampling and analysis are also presented in this chapter, if the State performed sampling during the reporting year.

The Community Environmental Monitoring Program (CEMP), established by NNSA/NFO, also performs annual, independent radiological monitoring of water supply systems in communities surrounding the NNSS and emphasizes community involvement. This independent outreach program is managed by the Desert Research Institute (DRI). The reader is directed to Chapter 7 for the presentation of CEMP's water monitoring activities in 2014.

5.1 Radiological Monitoring

Radionuclides have been detected in the groundwater in some areas of the NNSS as a result of historical underground nuclear tests. Between 1951 and 1992, 828 of these tests were conducted, and approximately one-third were detonated near or in the saturated zone (U.S. Department of Energy, Nevada Operations Office 2000). The FFACO (as amended) established underground test area (UGTA) corrective action units (CAUs) that geographically group the underground nuclear tests on the NNSS (Figure 5-1). *Attachment A: Site Description* (included on the compact disc of this report and at <http://www.nv.energy.gov/library/publications/aser.aspx>) provides a thorough description of the complex hydrogeological environment in which underground nuclear testing was conducted.

NNSA/NFO is tasked, under the FFACO, with developing UGTA CAU-specific models of groundwater flow and radionuclide transport. These models are used to develop contaminant boundaries within which radiological contaminants are forecasted to exceed the Safe Drinking Water Act (SDWA) limits at any time within a 1,000-year period. The current status of the CAU-specific models of groundwater flow and contaminant transport is discussed in Section 11.1.2 of Chapter 11 of this report. Groundwater sampling and analyses support the development and evaluation of these models and demonstrate that there is no impact to public water sources as a result of underground nuclear testing. Other NNSS wells and surface waters are monitored by NNSA/NFO to demonstrate compliance with State-issued water discharge permits; with DOE Order 458.1, "Radiation Protection of the Public and the Environment;" with protection of groundwater from ongoing radiological waste disposal activities; and to demonstrate that the onsite drinking water supply is below SDWA radionuclide limits.

In 2013, the NNSS Integrated Groundwater Sampling Plan (NNSA/NFO 2014), referred to hereafter as the Plan, was designed to provide a comprehensive, integrated approach for collecting and analyzing groundwater samples that would meet NNSA/NFO's radiological water monitoring objectives associated with underground nuclear testing (see text box on page 5-3). The Plan produced changes to the overall number of NNSA/NFO groundwater sampling locations, their sampling frequency, and the analytical procedures performed. The Plan will increase efficiencies and cost savings and standardize sampling methods and analyses performed for NNSA/NFO by

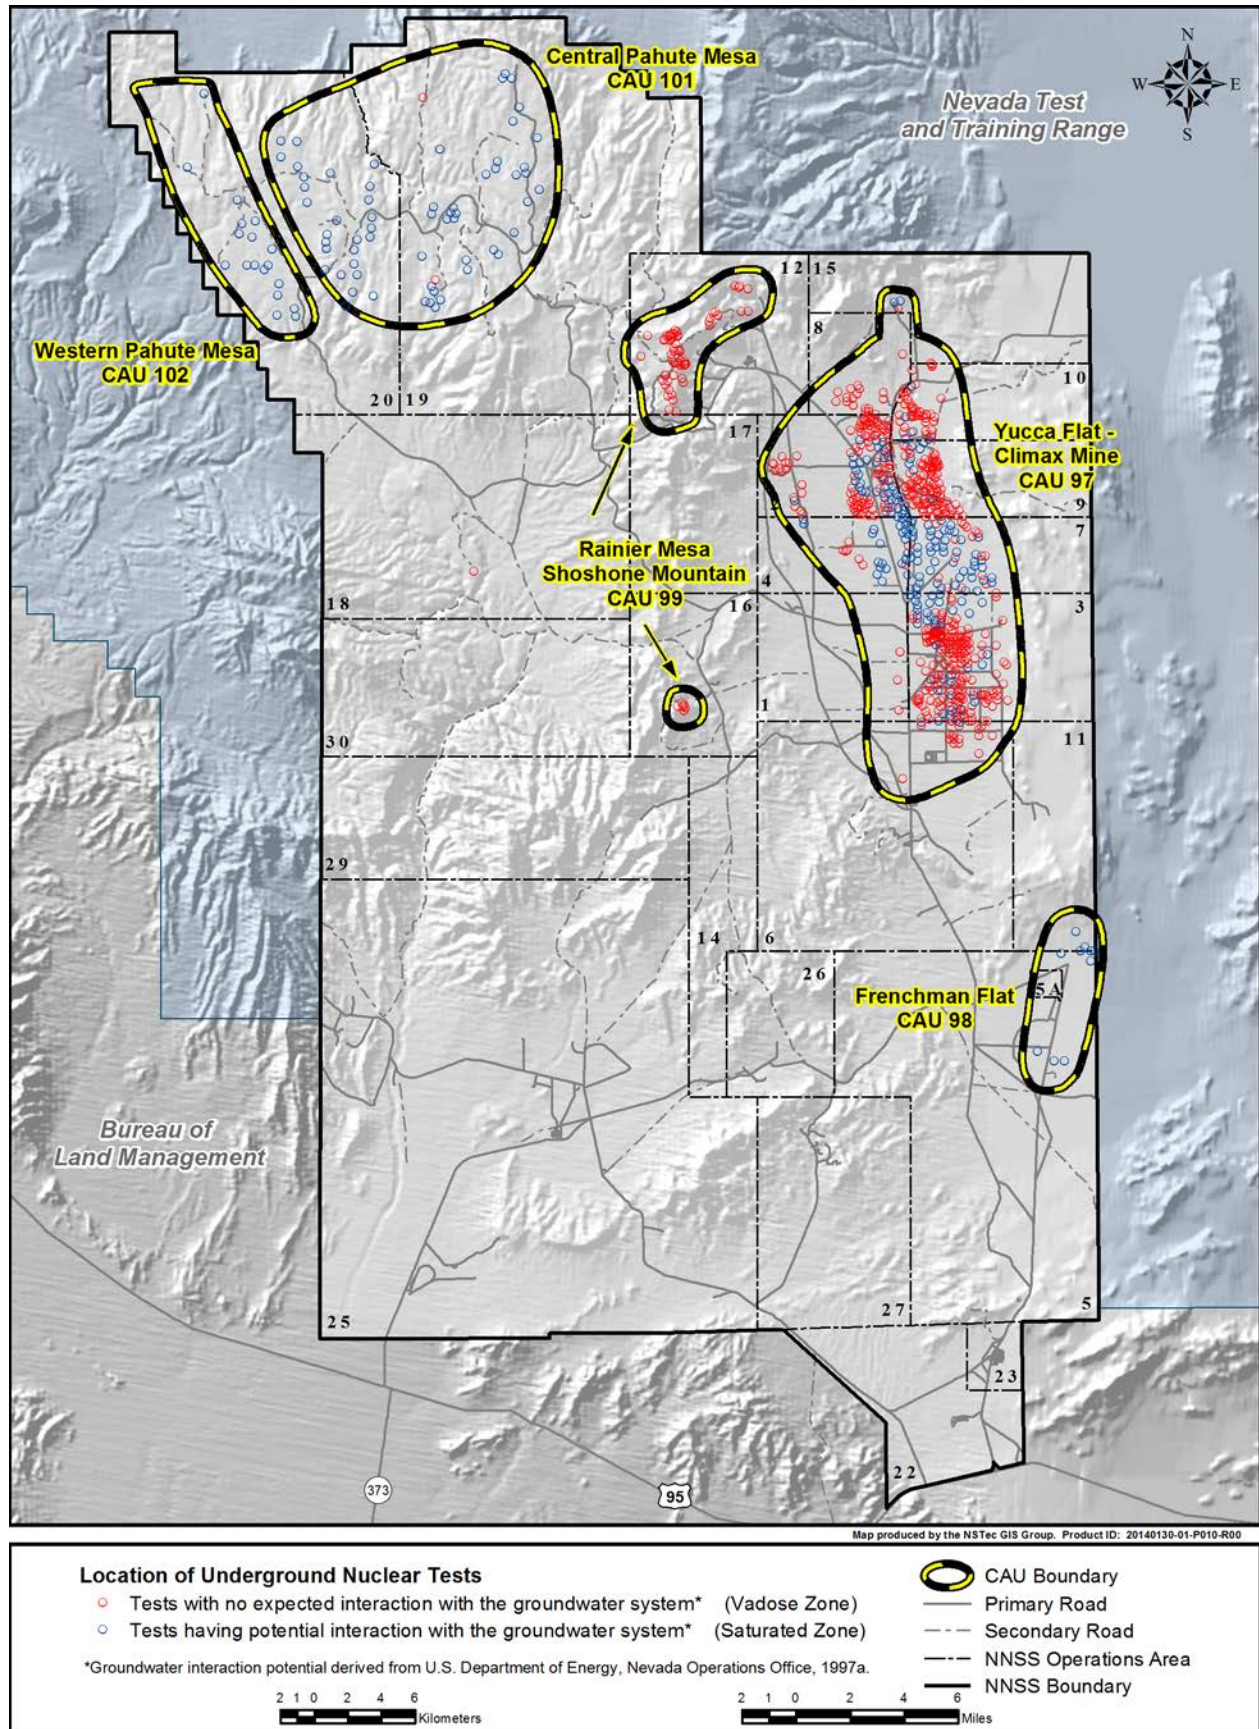

Figure 5-1. Locations of underground nuclear tests and UGTA CAUs on the NNSS

numerous organizations, contractors, and subcontractors. The Plan also ensures routine sampling of wells that are critical to understanding contaminant transport near the underground nuclear testing areas. Transition to Plan implementation began in Spring 2013. This chapter presents the Plan's design, the most recent tritium analysis results for wells sampled under the Plan, and other 2014 water analysis results related to meeting NNSA/NFO's radiological water monitoring objectives.

Radiological Water Monitoring Objectives

Provide data to complete corrective actions prescribed under the FFACO to protect the public from groundwater contaminated by historical underground nuclear testing (see Table 5-1 for objectives specific to each type of sampling location).

Identify and evaluate trends in radionuclide concentrations in water supply wells on the NNSS (referred to as onsite wells).

Determine compliance with the dose limits to the general public set by DOE O 458.1 via the water pathway (see Chapter 9 for estimates of public dose).

Determine compliance with wastewater discharge permit limits for radionuclides at permitted NNSS facilities.

Monitor wells downgradient of an NNSS radioactive waste disposal unit in accordance with a Resource Conservation and Recovery Act (RCRA) permit to ensure wastes do not impact groundwater.

5.1.1 Groundwater Sampling and Analyses

The radiological water sampling network consists of 84 sample locations, categorized into seven different types. Table 5-1 defines each sample source type and the monitoring objectives, analytes, and sample frequency associated with each. Some locations are sampled to meet multiple objectives. The sampling network is shown in Figure 5-2.

The Plan focuses on evaluating the extent and movement of contaminants resulting from underground nuclear testing. Baseline data are established at downgradient locations (see the Regional Groundwater Flow System arrows in Figure 5-2 depicting groundwater flow direction and volume) so that the presence of radioisotopes is known with a high level of certainty well before they reach SDWA limits. Wells upgradient from the UGTA CAUs are not included in the sampling network. Also, no NNSS springs are included in the network. Ten NNSS springs have been monitored periodically and reported in past annual environmental reports. They include Cane, Captain Jack, Cottonwood, Gold Meadows, John's, Tipipah, Topopah, Tub, Twin, and Whiterock springs; see Figure A-4 of *Attachment A: Site Description* included on the compact disc of this report for the location of NNSS springs and seeps. The groundwater that feeds these onsite springs is locally derived and is not hydrologically connected to the aquifers that may be impacted by underground nuclear tests. Detectable man-made radionuclides in onsite springs are primarily from historical atmospheric testing activities, including global radioactive fallout (U.S. Department of Energy, National Nuclear Security Administration Nevada Site Office [NNSA/NSO] 2008).

Table 5-1. Type definitions and objectives for NNSA/NFO radiological water sample locations

Sample Source Type	Definition	Objective	Analytes	Frequency
Characterization	Used for system characterization or model evaluation	<ul style="list-style-type: none"> • Support development and/or evaluation of flow and transport models • Identify groundwater flow paths • Establish the presence or absence of groundwater contaminants of concern (COCs) and contaminants of potential concern (COPCs) • Estimate travel time of contaminants • To be reclassified and sampled according to its new type when above objectives are met 	Specific to UGTA Strategy stage (FFACO, as amended) for each UGTA CAU (may include general chemistry, metals, gamma emitters, age and migration parameters, gross alpha, gross beta, and other radioisotopes)	2–3 years, as needed

Table 5-1. Type definitions and objectives for NNSA/NFO radiological water sampling locations (continued)

Sample Source Type	Definition	Objective	Analytes	Frequency ^(a)
Source/Plume	Located within the plume from an underground nuclear test (i.e., test-related contamination present)	<ul style="list-style-type: none"> Support development and/or evaluation of flow and transport models Identify COCs for downgradient wells Monitor contaminant migration Monitor natural attenuation of radiological contaminants 	Radiological COCs and CAU-specific COPCs (see Table 5-2)	4 years
Early Detection	Located downgradient of an underground test and no radioisotopes detected above the minimum detection level for standard analysis	<ul style="list-style-type: none"> Support development and/or evaluation of flow and transport models Detect and monitor plume edge 	Tritium (³ H) (enriched analysis)	2–5 years
Distal	Downgradient of the Early Detection area	<ul style="list-style-type: none"> Monitor COC (³H) below SDWA 1,000 pCi/L detection limit Support development and/or evaluation of flow and transport models 	³ H (standard analysis)	5 years
Community	Located on Bureau of Land Management (BLM) or private land; used as a water supply source or is near one	<ul style="list-style-type: none"> Monitor COC (³H) below SDWA 1,000 pCi/L detection limit 	³ H (standard analysis)	5 years
NNSS PWS	Permitted water supply well that is part of a State-designated noncommunity public water system (PWS) on the NNSS	<ul style="list-style-type: none"> Monitor to demonstrate safety of NNSS drinking water (radiological monitoring is not required by the State for noncommunity PWSs) 	³ H (standard analysis), gross alpha, gross beta	Quarterly
Compliance	Sampled to comply with specific federal/state regulations or permits	<ul style="list-style-type: none"> Determine if radiological COCs are within permit limits 	As specified by permit	As specified by permit

(a) The sampling frequency can be as long as every 2–5 years because of known low groundwater velocity and the resulting slow change over time in radionuclide concentrations expected within certain wells.

5.1.1.1 Analytes

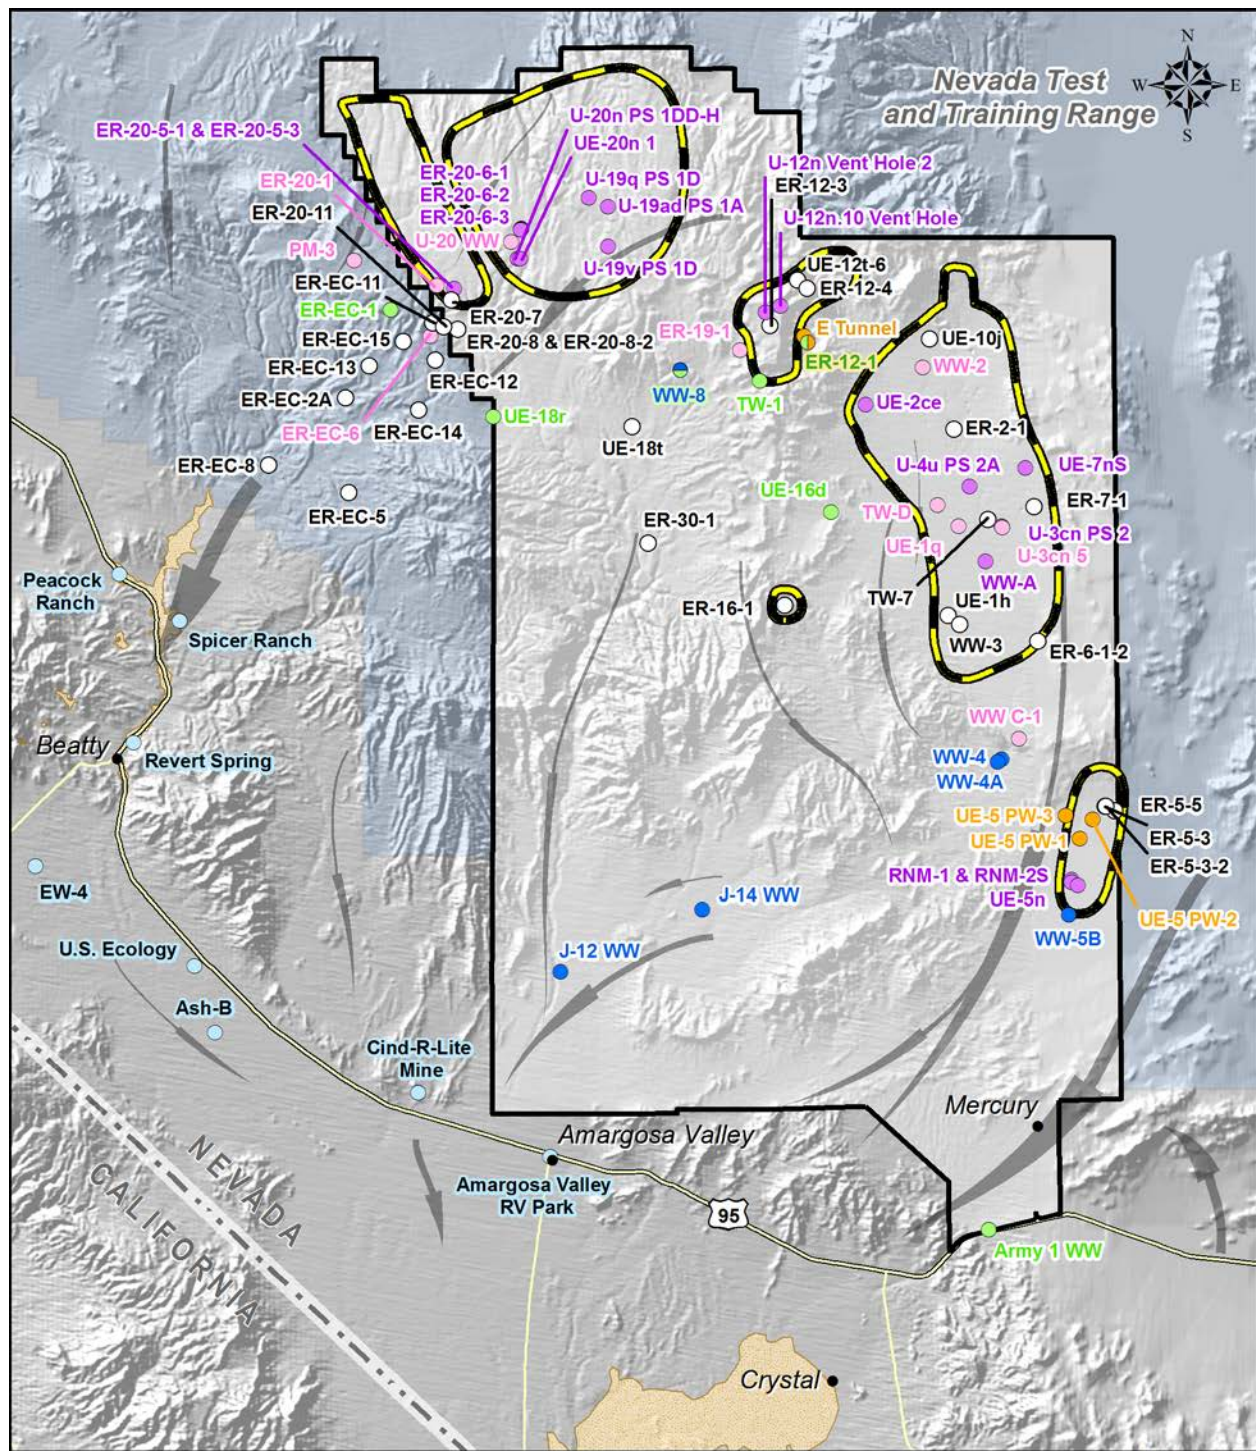

An inventory of 43 radionuclides produced by NNSS underground nuclear tests is presented in Bowen et al. (2001). Many of these radionuclides are relatively immobile because they are bound within the melt glass produced during nuclear detonation or have chemical properties that cause them to bind strongly to the aquifer rock materials. Those radionuclides that are most mobile in groundwater and are produced in high abundance from nuclear testing have the greatest potential for impacting groundwater quality.

A single contaminant of concern (COC) and, at some locations, additional contaminants of potential concern (COPCs) were identified based on the Bowen et al. (2001) inventory, an understanding of the radionuclide's relative mobility, previous sampling and analysis data, and modeling results (Table 5-2). Tritium (see Glossary, Appendix B) has been identified as the single COC for all sample locations based on extensive groundwater characterization data from wells throughout each CAU. The Plan therefore prescribes tritium analysis for all sampling locations at frequencies that range from every 2 to 5 years (Table 5-1). NNSS public water system (PWS) wells are sampled quarterly, and Compliance well sampling is consistent with the applicable permit requirements.

For all CAUs except Rainier Mesa/Shoshone Mountain, tritium is the only radionuclide included in the inventory that is known to have exceeded its SDWA maximum contaminant level (MCL) of 20,000 picocuries per liter (pCi/L) in sampling locations away from the nuclear test cavity (NNSA/NFO 2014). Although plutonium (Pu) has been reported above its SDWA MCL of 15 pCi/L in T Tunnel, located in Rainier Mesa (Zavarin 2009), it has not been detected in downgradient wells at concentrations above

Tritium is a radioactive form of hydrogen with a half-life of 12.3 years. The Safe Drinking Water Act (SDWA) limit for tritium in drinking water is 20,000 pCi/L.

pCi/L (picoCurie per liter) is a unit of measure used to express the amount of radioactivity in one liter of a gas or a liquid. A picoCurie is one-trillionth of a Curie, and 1 pCi/L is the amount of radioactive material in 1 liter of a gas or liquid that will produce 0.037 disintegrations per second. In the case of tritium, a disintegration is the emission of a beta particle.

Map produced by the NSTec GIS Group. Product ID: 20150211-0-P007-R00

Figure 5-2. NNSA/NFO water sampling network

10% of its SDWA MCL. Pu has therefore been identified as a COPC for the Rainier Mesa/ Shoshone Mountain CAU and is analyzed for in all Characterization and Source/Plume well samples in that CAU. Similarly, the other CAU-specific COPCs (Table 5-2) may have exceeded their SDWA MCLs in samples collected from the test cavity but have generally not exceeded 10% of their MCLs in downgradient locations.

Groundwater characterization data have shown that COPCs, if present, are at insignificant levels (i.e., < 0.1% of their MCL) unless tritium is present at concentrations that exceed its 20,000 pCi/L MCL. Therefore, COPCs are only analyzed in Source/Plume wells, where tritium exceeds the detection limit for standard tritium analysis (300 pCi/L). Instrumentation capable of detecting COPCs at levels well below their MCLs are used for their analysis in Source/Plume and Characterization well samples. This ensures that a baseline for COPC levels is established and that they will be detected early. Trends in the COPC data will be evaluated to determine whether a COPC should be reclassified as a COC and monitored in Early Detection wells. Samples collected from Characterization wells are analyzed for many of the immobile radionuclides listed in Bowen et al. (2001). These radionuclides have not been found near their SDWA MCL in any of the samples, including those collected from underground nuclear test cavities. While not analyzed routinely as part of the Plan, the suite of radionuclides will be periodically expanded for some Source/Plume wells to confirm that they are not present near their MCLs in groundwater in, or downgradient of, the underground nuclear test cavities.

Table 5-2. CAU-specific COCs and COPCs

CAU	COC ^(a)	COPC ^(b)
Frenchman Flat	³ H	¹⁴ C, ³⁶ Cl, ⁹⁹ Tc, and ¹²⁹ I
Pahute Mesa	³ H	¹⁴ C, ³⁶ Cl, ⁹⁹ Tc, and ¹²⁹ I
Rainier Mesa/Shoshone Mountain	³ H	¹⁴ C, ³⁶ Cl, ⁹⁰ Sr, ⁹⁹ Tc, ¹²⁹ I, and Pu
Yucca Flat/Climax Mine	³ H	¹⁴ C, ³⁶ Cl, ⁹⁹ Tc, and ¹²⁹ I (and ⁹⁰ Sr and ¹³⁷ Cs in the lower carbonate aquifer samples)

Note: See Chapter 1, Table 1-5 for a listing of full names and half-lives of radionuclide abbreviations listed.

(a) A radionuclide that has exceeded its SDWA MCL in sampling locations downgradient from a nuclear test cavity.

(b) A radionuclide that has the potential to become a COC based either on historical analytical data and/or on model results. COPCs may have exceeded SDWA MCLs in samples from a nuclear test cavity but have generally not exceeded 10% of their MCLs in sampling locations downgradient from a test cavity.

Gross alpha (α) and gross beta (β) radioactivity and gamma spectroscopy analyses have been conducted for some groundwater samples in the past according to a prescribed sampling schedule (see Table 5-1 of National Security Technologies, LLC [NSTec], 2012). During development of the Plan, a decision was made to analyze for gross alpha and gross beta radioactivity at Characterization wells to establish a baseline. They continue to be monitored for NNS PWS wells and for certain Compliance water sampling locations, as required.

5.1.1.2 Sample Collection Methods

Water sampling methods are based, in part, on the characteristics and configurations of sample locations. For example, wells with dedicated pumps may be sampled from the associated plumbing (e.g., spigots) at the wellhead, while wells without pumps may be sampled via a wireline bailer or a portable pumping system. The majority of wells sampled are single-zone completion wells where samples are collected from one depth. Some wells, however, are multiple-completion wells that are sampled at multiple depths (e.g., ER-EC-11, -12, -13, -14, and -15). All water samples are collected in a manner that ensures they represent ambient formation water following the sampling methods described in standard operating procedures. This may involve purging the well until the stability of certain water quality parameters (e.g., pH, temperature, electrical conductivity) is achieved. Stabilization of these water quality parameters indicates that formation water is being sampled instead of stagnant water from within and surrounding the wellbore.

5.1.1.3 Detection Limits

Samples collected from all Early Detection wells and from some Characterization wells, are enriched before being analyzed for tritium. These wells are expected to have tritium levels less than 300 pCi/L, which is the minimum detectable concentration (MDC) (see Glossary, Appendix B) using the standard Environmental Protection Agency

(EPA) (or un-enriched) analysis method (e.g., EPA 1980). The enrichment process (DOE 1997) concentrates tritium in a sample to provide lower MDCs, which range from approximately 2 to 40 pCi/L depending on the laboratory performing the enrichment process. For samples with expected levels of tritium above the laboratory's standard detection capability, or when the objective is to monitor for SDWA compliance, tritium enrichment is not performed. The MDCs for standard tritium analyses is approximately 300 pCi/L, which is well below the EPA's SDWA required detection limit of 1,000 pCi/L for tritium. Standard methods are used for analysis of COPCs and are performed by State of Nevada certified commercial laboratories. The MDCs must be at or below the SDWA MCL. The MDCs for gross alpha and beta radioactivity are 2 and 4 pCi/L, respectively, and satisfy their EPA SDWA required detection limits of 3 and 4 pCi/L, respectively.

Highly sensitive instrumentation at Lawrence Livermore National Laboratory (LLNL) is used to analyze tritium concentrations in Characterization and Early Detection wells, when standard methods are not sufficient (i.e., tritium is expected to be at levels less than the 300 pCi/L MDC for the standard method). LLNL's instrumentation is capable of detecting tritium at concentrations less than 1 pCi/L. Similarly, LLNL uses highly sensitive methods for COPC analyses for samples from Source/Plume and Characterization wells. These methods are capable of measuring natural levels of some COPCs (^{14}C and ^{36}Cl) in the groundwater.

Analytical methods routinely include quality control samples such as duplicates, blanks, and spikes. Chapter 16 discusses in more detail the quality assurance and control procedures used for sampling and analyzing groundwater.

5.1.2 Presentation of Water Sampling Data

The maximum tritium concentration which has been measured in each well in the Plan's sampling network is used to classify each well into one of four concentration levels relative to its percentage of the 20,000 pCi/L SDWA MCL (Table 5-3). In Figure 5-3, each of the four categories are color-coded in order to depict spatially the levels of tritium among all sampling locations. The fifteen wells that currently exceed the SDWA MCL (coded red on Figure 5-3) are all located on the NNSS and are either Source/Plume or Characterization wells. All Community sampling locations, which are on BLM or private land, have undetectable levels of tritium (coded blue on Figure 5-3).

Table 5-3. Tritium concentration categories

Tritium Concentration (X) in pCi/L	Percent of SDWA MCL
$X < 1,000$	< 5
$1,000 < X < 10,000$	5–50
$10,000 < X < 20,000$	50–100
$X > 20,000$	> 100 (Exceeds SDWA MCL)

Table 5-4 presents the maximum tritium concentration data used to create the color-coded categories shown in Figure 5-3. Table 5-4 groups the sampling location data by CAU and then by sample location type. When tritium was not detected, the value is reported in Table 5-4 as less than the sample's MDC (i.e., <MDC). For wells at which multiple samples were collected and analyzed during a single year, Table 5-4 presents the result for the sample that had the highest tritium concentration. Similarly, for wells that are sampled at multiple depths during a single year, Table 5-4 presents the result for the depth sample that had the highest tritium. The results of analyses for those radionuclides identified as COPCs (Table 5-2) are not tabulated in this report but can be acquired upon request from NNSA/NFO.

The tritium, gross alpha, and gross beta levels for water samples collected and analyzed in 2014 for the NNSS PWS and Compliance sampling locations are presented in Table 5-5.

(a) Concentrations presented as less than (<) a number, indicate that tritium levels are less than its sample-specific MDC shown.

(b) The Frenchman Flat Characterization well ER-11-2 was removed in 2014 from the sampling plan (see Chapter 11, Section 11.1.1.1).

(c) The standard (un-enriched) tritium analysis method was used (see Section 5.1.1.3). Prior to 2013, the enrichment process, resulting in lower MDCs, was not routinely used for analyses of all Characterization well samples.

(d) The enriched tritium analysis method was used, but sample MDC is atypically high.

(e) NA = not applicable.

(f) ER-12-1 is also a Compliance well (see Table 5-5).

(g) WW-8 is also a NNSS PWS well (see Table 5-5).

(a) Concentrations presented as less than (<) a number, indicate that tritium levels are less than its sample-specific MDC shown.

(b) FD = field duplicate sample.

(c) NA = not applicable, analysis was not performed.

(d) ER-12-1 is sampled once every 24 months, it was not scheduled for sampling in 2014.

5.1.3 Discussion of 2014 Sample Results

The following subsections discuss the analytical results for the seven well types that comprise the radiological water sampling network. In addition, results are presented for samples collected from two wells of interest to UGTA but not in the Plan (i.e., inactive wells, Section 5.1.3.8). As illustrated in Figure 5-2, all Characterization, Source/Plume, Early Detection, and Distal wells are located on government-owned property. All Community wells or springs are located on BLM or private land. As reflected in Table 5-4 and presented in the sections below, no test-related radionuclides are present in the Distal or Community wells. Consistent with the definition of Early Detection wells (tritium levels are less than 300 pCi/L), low concentrations of tritium at a few locations have been detected in these wells. Sampling results from PWS wells located on the NNSS indicate that water sources used by NNSS personnel are not affected by underground nuclear tests. In addition, all regulatory requirements associated with the Compliance well samples were satisfied.

5.1.3.1 Characterization Wells

Twenty-eight Characterization wells are currently included in the sampling network. They are either new wells, or wells that require additional radionuclide data to establish a baseline and/or to ensure that the current list of COCs and COPCs (Table 5-2) is accurate for the CAU. Once a baseline has been developed, each Characterization well will be reclassified and sampled according to its new type (Source/Plume, Early Detection, Distal, or Community).

Frenchman Flat CAU - Two Characterization wells are present in this CAU (Table 5-4). ER-5-3 is located nearest to five underground tests (UGTs). It was last sampled in 2001 and no tritium was detected. ER-5-5, the second Characterization well in this CAU, was drilled in 2012, along with well ER-11-2. They were both drilled near detonation points in order to evaluate the Phase II flow and contaminant transport models (see Section 11.1.1.1). Low-level tritium was detected in ER-5-5 in 2013 (1.1 pCi/L, Table 5-4), which was forecasted by the models (Navarro Nevada Environmental Services, LLC, 2010), although no tritium was detected in ER-11-2. Based on extensive data and model reviews, ER-11-2 was dropped from the water sampling network (see Section 11.1.1.1). Neither ER-5-3 nor ER-5-5 were sampled in 2014.

Pahute Mesa CAUs - Twelve Characterization wells are associated with the Central and Western Pahute Mesa CAUs, and six of them were sampled in 2014 (Table -3). Most of these wells were drilled in 2009 through 2012 as part of the Phase II corrective action investigation for this CAU (see Section 11.1.1.2). Tritium has been detected in six of the wells (ER-20-7, ER-20-8, ER-20-8-2, ER-EC-6, ER-20-11, ER-EC-11, and ER-EC-12).

Elevated tritium concentrations (10,600 pCi/L) were found in ER-EC-11 in 2009 during the well's first year of sampling. It was the first offsite well beyond NNSS boundaries in which a radionuclide from NNSS UGTs had been detected. Well ER-EC-11 is 716.3 m (2,350 ft) west of the NNSS boundary. Casing had been installed in ER-EC-11 below the depth where the high tritium was observed in 2009 in order to prevent cross contamination to the deeper aquifers open to this well. The casing, however, prevented developing and further sampling this shallower depth. Recently, technology has become available for sampling narrow diameter piezometers such as those installed in ER-EC-11 for taking water-level measurements. In 2014, this technology was used to purge and sample the piezometer accessing the same shallow aquifer as sampled in 2009. The resulting tritium concentration was 16,100 pCi/L. This sample is considered more representative of the tritium in this aquifer than the bailed sample collected in 2009.

Tritium was detected in Well ER-EC-11 in 2009 at 10,600 pCi/L. This was the first time that a radionuclide from NNSS UGTs had been detected in groundwater beyond NNSS boundaries. In 2014, it was detected at 16,100 pCi/L. This concentration is below the allowable drinking water limit of 20,000 pCi/L set by the EPA.

The highest tritium concentration among the Characterization wells of the Pahute Mesa CAUs is at Well ER-20-7, sampled in 2014 (15,600,000 pCi/L; Table 5-4). This well is located 960 m (3,150 ft) and 2,100 m (6,890 ft) from the boreholes U-20y and U-20c, the detonation points for the Tybo and Benham UGTs, respectively. The tritium concentration in ER-20-7 decreased from 19,100,000 pCi/L, as measured in 2010. This decrease is primarily a result of tritium decay over the 4-year time period but may also indicate tritium movement away from the well. Tritium in ER-20-7, ER-20-1, ER-EC-11, ER-20-8, and ER-20-8-2 (Table 5-4) is believed to represent a

downgradient extension of the Benham-Tybo contaminant plume (see Section 11.1.1.2). For wells ER-20-8 and ER-20-8-2, which were sampled in 2014, tritium concentrations increased from their earlier reported values: from 3,020 pCi/L in 2011 to 8,800 pCi/L in 2014 for ER-20-8 and from 1,280 pCi/L in 2009 to 2,670 pCi/L for ER-20-8-2. Different techniques were used to collect these samples, which may be partially responsible for the increases. These results are presently being evaluated.

Groundwater at Well ER-EC-12 contained a very low concentration of tritium when it was last collected in 2012 (4.2 pCi/L; Table 5-4). Additional sampling and analyses is needed to confirm this marginally measureable amounts of tritium. Tritium has not been detected in the other Characterization wells within the Pahute Mesa CAUs; these wells will be categorized as Early Detection or Distal wells depending on their proximity to the UGTs and Source/Plume wells once characterization is complete.

Rainier Mesa/Shoshone Mountain CAU - Six Characterization wells are located within this CAU (Table 5-4). None were sampled in 2014. The tritium concentrations previously reported for these wells are either near or below sample-specific MDCs, using the standard tritium analysis method (see Section 5.1.1.3). Future sample analyses of Characterization wells in this CAU (and in all other CAUs) will use the tritium enrichment analysis method to verify the presence or absence of tritium at the lower MDC. These wells will likely be re-categorized as Early Detection or Distal wells depending on the presence/absence of tritium and their relative proximity to the UGTs once characterization is complete.

Yucca Flat/Climax Mine CAU - Eight Characterization wells are located within this CAU, and three were sampled in 2014 (Table 5-4). A very low concentration of tritium (7.3 pCi/L) was detected in Well WW-3, and is thought to result from seepage from an adjacent surface-water pond rather than from an underground nuclear test. Additional sampling of this well is planned for 2015. Samples collected from Well ER-2-1 in 2003 were analyzed by LLNL for tritium using the helium accumulation method which results in an MDC of approximately 1 pCi/L. The presence of tritium was expected in this well because it is located within 1 mile of 62 nuclear tests, 19 of which are near or below the water table. Five of the tests, which were below the water table, were within 1,500 ft of ER-2-1. Future use of the tritium enrichment analysis method for Characterization wells in this CAU (e.g., in ER-6-1-2 and UE-10j) will verify the presence or absence of tritium at the lower MDC. These wells will likely be re-categorized as Early Detection or Distal wells depending on the presence/absence of tritium and their relative proximity to the UGTs once characterization is complete.

5.1.3.2 Source/Plume Wells

Twenty Source/Plume wells are included in the sampling network. They have detectable radionuclides from NNSS underground nuclear testing and vary in location from within a test cavity where radionuclide concentrations are high, to downgradient of the detonation where radionuclide concentrations can be relatively low, in comparison to SDWA MCLs. Samples are collected every 4 years (three samples per one tritium half-life) and analyzed for tritium and CAU-specific COPCs (Table 5-2). Three Source/Plume wells, all within the Frenchman Flat CAU, were sampled in 2014.

Frenchman Flat CAU - Three Source/Plume wells are located in this CAU, and all were sampled in 2014. Two of the wells exceed the 20,000 pCi/L MCL for tritium (Table 5-4; Figure 5-3). In 1974, RNM-1 was drilled directly into the explosion region of the underground nuclear test Cambric, which was detonated in 1965. Well RNM-2S was also drilled 91 m (300 ft) south of the Cambric shot point in 1974. To evaluate radionuclide migration, groundwater flow from the detonation point to Well RNM-2S was induced by pumping Well RNM-2S from 1975 to 1991 (Bryant 1992). Tritium concentrations decreased in RNM-1 and increased in RNM-2S as a result of the pumping experiment (Stoller-Navarro Joint Venture [SNJV] 2005). Well UE-5n is located approximately 560 m (1,840 ft) southeast of RNM-1 within an unlined discharge ditch that was used to transport large volumes (approximately 1.7×10^7 cubic meters) of water pumped during the experiment (Finnegan and Thompson, 2002). Radionuclides detected in UE-5n waters are thought to reflect infiltration of water from the unlined ditch rather than groundwater transport from the test cavity (Rose et al. 2003). While groundwater samples from RNM-1 have exceeded the MCL for a few radionuclides (^{90}Sr , ^{137}Cs , and ^{129}I), only tritium has exceeded its MCL in groundwater from RNM-2S and UE-5n. In fact, two of the radionuclides, ^{90}Sr and ^{137}Cs , were not detected in RNM-2S even after 16 years of pumping (SNJV 2005) and are therefore not COPCs for this CAU.

The tritium concentrations in the 2014 samples from these three Source/Plume wells were all lower than the 2007 values of 866 and 104,000 pCi/L for RNM-1 and RNM-2S, respectively, and lower than the 2010 value of 186,000 pCi/L for UE-5n. The decreasing concentrations are consistent with tritium decay over the 7-year (RNM-1 and RNM-2S) and 4-year (UE-5n) time periods. None of the COPCs were detected in the 2014 water samples.

Pahute Mesa CAUs - Ten Source/Plume wells, associated with six different UGTs, occur within the Central and Western Pahute Mesa CAUs (Table 5-4). None of these wells were sampled in 2014. The groundwater in all but two wells (ER-20-6-1 and ER-20-6-3) exceed the tritium MCL (Table 5-4; Figure 5-3). A few radionuclides (^{90}Sr , ^{137}Cs , ^{129}I , and Pu) exceed their SDWA MCLs (8, 200, 1, and 15 pCi/L, respectively) in samples from wells drilled directly into a test cavity (U-19ad PS 1A, U-19v PS 1D, and U-20n PS 1DD-H). They have not, however, exceeded their MCLs in wells located away from the test cavity, even when the wells are within 300 m of the cavity (U-19q PS 1D and UE-20n 1) and when high levels of tritium were detected (Table 5-4). In samples from U-19q PS 1D and UE-20n 1, only ^{14}C was found at levels $\geq 10\%$ of its SDWA MCL of 2,000 pCi/L.

Rainier Mesa/Shoshone Mountain CAU - Two Source/Plume locations are monitored within the Rainier Mesa/Shoshone Mountain CAU but were not sampled in 2014 (Table 5-4). They are two historical N Tunnel vent holes. The N Tunnel complex was sealed in 1994 and became flooded with groundwater, which is sampled through the vent holes to monitor radionuclides within the tunnel complex. While tritium was observed above the MCL in these vent holes (Table 5-4), no other radionuclides were observed above their MCLs. In these Source/Plume locations, ^{90}Sr , ^{129}I , and Pu are within 10% of their SDWA MCLs.

Yucca Flat/Climax Mine CAU - Five Source/Plume wells occur within the Yucca Flat/Climax Mine CAU (Table 5-4). None were sampled in 2014. Two of the wells are drilled directly into a test cavity (U-3cn PS 2 and U-4u PS 2A); groundwater from these wells exceed the 20,000 pCi/L MCL for tritium. Two other Source/Plume wells (UE-2ce and UE-7nS) are located within 200 m (655 ft) from detonation cavities, but groundwater from only Well UE-2ce exceeds the tritium MCL. Well WW-A is located approximately 520 m (1,705 ft) from a test cavity. Tritium was detected in WW-A in the late 1980s, peaked at ~ 700 pCi/L in 1999, and declined to 355 pCi/L by 2012 (Table 5-4). The combined presence of four radionuclides (^{14}C , ^{90}Sr , ^{137}Cs , and ^{129}I) in Well U-4u PS 2A exceeds the SDWA MCL for beta- and photon-emitting radionuclides allowed in drinking water, which is the combined concentration of such emitters that would result in an exposure of 4 mrem/yr. No other radionuclides in samples from Source/Plume wells in this CAU exceed the SDWA MCL. No radionuclides have been found at levels $\geq 10\%$ of their SDWA MCLs in wells located away from a test cavity within the Yucca Flat/Climax Mine CAU, except for ^{90}Sr in Well UE-2ce.

5.1.3.3 Early Detection Wells

Ten Early Detection wells are included in the sampling network (Table 5-4). They are the next wells down-gradient of a UGT or Source/Plume well and have tritium levels less than the MDCs for standard tritium analyses (i.e., < 300 pCi/L). In the absence of tritium, no other test-related radionuclides are present in historically sampled groundwater; therefore, Early Detection Wells are monitored solely for low levels of tritium using enriched tritium analysis. Most of these wells are sampled every 2 years to ensure that the plume front is detected in a reasonable time frame and that a time trend for tritium is established early. In some cases (e.g., for Frenchman Flat Early Detection wells, once they are identified), the sampling frequency will be once every 5 years because of low groundwater velocity within this CAU and the resulting slow change in radionuclide concentration with time.

Only two Early Detection wells, PM-3 and ER-EC-6, were sampled in 2014, both down-gradient from the Central and Western Pahute Mesa CAUs. In 2012, groundwater samples from PM-3 were collected using depth-discrete bailers at depths of 475.5 m (1,560 ft) and 607.8 m (1,994 ft). These bailed water samples were found to contain very low concentrations of tritium (64.6 and 52.9 pCi/L, respectively). In 2013, a pump was installed in PM-3 and a total of 82,518 gallons of groundwater was purged in order to develop the well. Samples were collected once the water quality parameters stabilized. The results confirmed the presence of tritium from the depth-discrete bailed water samples collected in 2012. The 2013 samples from the shallow interval had tritium levels ranging from 225 to 249 pCi/L and from the deep interval ranging from 37 to 44 pCi/L. In 2014, PM-3 was sampled using a depth-discrete bailer from a depth of 475.5 m (1,560 ft) and the tritium concentrations (216 and 237 pCi/L) were similar to those reported in 2013. The highest 2014 value of 237 pCi/L is shown in Table 5-4. Samples were also bailed from a depth of 604.4 m (1,983 ft) and the tritium concentration was reported as 39.0 pCi/L, which is also

quite similar to the 2013 results for samples from a similar depth. Preliminary evidence indicates that the tritium may be from the Handley UGT, a test with a yield greater than one megaton, which was detonated in 1970 and is located about 7.2 km north–northeast and upgradient of PM-3.

5.1.3.4 Distal Wells

Seven Distal wells occur within the sampling network (Table 5-4). Distal wells are analyzed for tritium using the standard EPA method. Samples are collected at a 5-year frequency. The sampling objective for these wells is to demonstrate that tritium is not present downgradient of UGTs at levels above the SDWA-required minimum detection limit of 1,000 pCi/L. These wells also support the development and evaluation of the flow and contaminant transport models. Two Distal wells, ER-12-1 and WW-8, were sampled in 2014. ER-12-1 is also a Compliance well, and WW-8 is also an NNSS PWS well. No tritium was detected in any of the 2014 samples (Tables 5-4 and 5-5).

5.1.3.5 Community Wells/Springs

Eight Community sampling locations occur within the sampling network (Table 5-4). None were sampled in 2014. These wells and springs are either used as private, business, or community water supply sources or are near such sources, and they are sampled for tritium every 5 years. Sampling at a 5-year frequency is sufficient because of the long flow paths to these locations, the low groundwater velocities, and the monitoring of Early Detection wells upgradient from the Community wells and springs. Early Detection well samples will detect the arrival of a contaminant plume at very low concentrations (i.e., measuring tritium at 0.01% of its MCL) long before such a plume could be detected in these private, business, or community water supply sources. Samples are analyzed using a standard EPA method. The objective is to demonstrate that tritium is not present at levels above the SDWA-required minimum detection limit of 1,000 pCi/L. Well Ash B was last sampled in 2009, Well EW-4 was last sampled in 2011, and the other six Community sampling locations were last sampled in 2012. No tritium has been detected in any of these wells (Table 5-4).

5.1.3.6 NNSS PWS Wells

Results from the NNSS water wells sampled quarterly in 2014 continue to indicate that historical underground nuclear testing has not impacted the NNSS water supply network. No tritium measurements were above their MDCs using the EPA standard analysis method (Table 5-5). Gross alpha and gross beta radioactivity were found at concentrations slightly greater than their MDCs in most 2014 samples and are believed to represent the presence of naturally occurring radionuclides. However, no water supply samples had gross alpha measurements that exceeded the EPA MCL (15 pCi/L) or gross beta measurements that exceeded the EPA level of concern (50 pCi/L).

5.1.3.7 Compliance Wells/Groundwater Discharges

5.1.3.7.1 RCRA Permitted Wells for the Area 5 Mixed Waste Disposal Unit

Wells UE-5 PW-1, UE-5 PW-2, and UE-5 PW-3 are sampled semi-annually for tritium. They are monitored for tritium and nonradiological parameters (see Section 10.1.7) to verify the performance of the Area 5 Mixed Waste Disposal Unit (Cell 18), which is operated under a RCRA permit. In 2014, all water samples, with the exception of the August field duplicate sample from UE-5 PW-2, had non-detectable levels of tritium (Table 5-5), indicating that Cell 18 radioactive wastes have not contaminated local groundwater. The August UE-5 PW-2 field duplicate sample result for tritium was considered to be anomalous, based on lack of any operational indication of a release, the value's close proximity to the MDC, the grab result being less than the MDC, and historical trends. Table 10-3 in Chapter 10, Section 10.1.7 presents the 2014 sampling results for four additional indicators of groundwater contamination, and all 2014 sample analysis results for these three wells are presented in NSTec (2015).

5.1.3.7.2 NDEP Permitted E Tunnel Waste Water Disposal System (ETDS)

NNSA/NFO manages and operates the ETDS in Area 12 under a water pollution control permit (NEV 96021) issued by the Nevada Division of Environmental Protection (NDEP) Bureau of Federal Facilities. The permit governs the management of radionuclide-contaminated wastewater that drains from the E Tunnel portal into a series of holding ponds. The permit requires Well ER-12-1 groundwater to be monitored once every 24 months and E Tunnel

discharge waters (retained in the E Tunnel Ponds) to be monitored once every 12 months for tritium, gross alpha, and gross beta as well as for numerous nonradiological parameters (see Section 5.2.4, Table 5-9).

On October 14, 2014, annual sampling of ETDS discharge water was performed. The permissible limits for tritium, gross alpha, and gross beta in the tunnel discharge waters are 1,000,000, 35.1, and 101 pCi/L, respectively. All E Tunnel Pond samples collected and analyzed in 2014 were below these limits allowed under the permit (Table 5-5).

5.1.3.7.3 UGTA Well Discharged Groundwater and Fluids

UGTA wells are regulated by the State through an agreement between NNSA/NFO and NDEP called the UGTA Fluid Management Plan (Attachment 1 of NNSA/NSO [2009]) in lieu of having separate State-issued water pollution control permits for each well. The plan prescribes the methods of disposing groundwater and fluids pumped from UGTA wells during drilling, development, and testing based on the levels of radiological contamination. Discharge water and drilling fluids having $\geq 400,000$ pCi/L of tritium are diverted to lined sumps to evaporate; otherwise they are diverted to unlined sumps to evaporate. Samples of the discharge water from the wellhead or bailer are analyzed for gross alpha, gross beta, tritium, and RCRA-regulated metals to ensure discharged water is below the established fluid management criteria for these parameters. When discharge water and drilling fluids are $\geq 400,000$ pCi/L of tritium, lead is monitored in the field to ensure that the RCRA limit for lead of 5 milligrams per liter (mg/L) is not exceeded; exceeding this level may result in the generation of a hazardous or mixed waste in a sump and in the suspension of drilling operations.

In 2014, well development and testing was conducted at ER-EC-14 and ER-EC-15, and pumped groundwater was directed to unlined sumps in accordance with the fluid management plan. Fluids in excess of sump capacity were allowed to gravity flow from the sumps to designated surface infiltration areas. Similarly, groundwater purged from wells sampled in 2014 was directed to unlined sumps, with the exception of groundwater purged from ER-20-7. Because of the high tritium concentration at ER-20-7 (Table 5-5), groundwater from this well was diverted to a lined sump in accordance with the fluid management plan. Grab samples from all sumps were below the fluid management criteria limits for all analyzed parameters.

5.1.3.8 UGTA Inactive Wells

Wells that have not been assigned to one of the seven previously discussed water sample location types are called inactive wells; they are not included in the NNSA/NFO water sampling network. In 2014, two inactive wells were sampled to evaluate past reports of low-level tritium concentrations. A sample collected from WW-5a in Frenchman Flat in 2000 had a tritium concentration of 1.5 pCi/L, as measured by LLNL using the helium accumulation method. This level was near its MDC for this analysis and was suspected of being associated with analytical uncertainty rather than with the actual presence of tritium due to its migration from the UGTs in the Frenchman Flat CAU. No tritium was detected by LLNL using the same method in the 2014 WW-5a sample, confirming that tritium is not present at this well. The detection limit for this sample was 1 pCi/L. Similarly, ER-6-2, within the Yucca Flat/Climax Mine CAU, was reported to have a tritium concentration of 92 pCi/L from a 2004 sample. The presence of tritium in this sample was thought to result from post-sampling contamination in the laboratory. No tritium was detected in the 2014 samples from this well using the enriched tritium method with detection limits of 1.8 and 2.2 pCi/L for duplicate sample analyses. This verifies that the previously reported value did not represent the actual tritium concentration in ER-6-2 groundwater.

5.1.4 Environmental Impact

The potential radiological impact to water resources from past activities on the NNSS is the migration of radionuclides in the groundwater downgradient from the UGTA CAUs. Currently, sampling and analysis data indicate that underground nuclear testing only within the Pahute Mesa CAUs has impacted groundwater off the NNSS; tritium has been detected above the tritium standard analysis method MDC of 300 pCi/L in one UGTA well on NTTR (ER-EC-11). Current data indicate, however, that the distance over which radionuclides have migrated from underground nuclear testing in the Pahute Mesa CAUs is not significant relative to the distance to offsite public water supply wells. Six Characterization wells within the Pahute Mesa CAUs intercept a contaminant plume of tritium believed to originate from the Tybo and Benham UGTs. These six well are within 900 ft to 17,000 ft (3.2 miles) of these two UGTs. Well sampling to date has not detected the presence of man-made radionuclides

downgradient of Pahute Mesa in nine other UGTA wells on the NTTR. As presented in previous annual reports, samples from offsite monitoring wells in Oasis Valley, farther downgradient of Pahute Mesa, also contain no detectable man-made radionuclides. These sampling results are consistent with UGTA's Phase I Pahute Mesa flow and transport model (SNJV 2009), which forecasts migration of tritium off the NNSS within 50 years of the first nuclear detonation (1965) from the Central and Western Pahute Mesa CAUs (see Section 11.1.2.2, Figure 11-4).

Currently, groundwater contaminated from historical UGTs does not impact the public or NNSS workers who drink water from wells located off or on the NNSS. However, NNSS wildlife are exposed to tritium in their drinking water or aquatic habitats from the NDEP-approved method of containing contaminated waters in the E Tunnel ponds and in sumps that may be used to contain pumped groundwater from UGTA wells. The potential dose to NNSS biota from these water sources is assessed annually (see Section 9.2), and the results demonstrate that the doses to biota are below the limits set to protect plant and animal populations (Bechtel Nevada 2004; NSTec 2008).

5.2 Nonradiological Drinking Water and Wastewater Monitoring

The quality of drinking water and wastewater on the NNSS is regulated by federal and state laws. The design, construction, operation, and maintenance of many of the drinking water and wastewater systems are regulated under state permits. NNSA/NFO ensures that such systems meet the applicable water quality standards and permit requirements (see Section 2.3). The NNSS nonradiological water monitoring goals are shown below. They are met by conducting field water sampling and analyses, performing assessments, and maintaining documentation. This section describes the results of 2014 activities. Information about radiological monitoring of drinking water on and off the NNSS and wastewater on the NNSS is presented in Sections 5.1.3.5 and 5.1.3.6.

Nonradiological Water Monitoring Goals

Ensure that the operation of NNSS public water systems (PWSs) and private water systems (see Glossary, Appendix B) provides high-quality drinking water to workers and visitors of the NNSS.

Determine if NNSS PWSs are operated in accordance with the requirements in Nevada Administrative Code NAC 445A, "Water Controls," under permits issued by the State.

Determine if the operation of septic systems that process domestic wastewater on the NNSS meets operational standards in accordance with the requirements NAC 445A under permits issued by the State.

Determine if the operation of industrial wastewater systems on the NNSS meets operational standards of federal and state regulations as prescribed under the GNEV93001 state permit.

5.2.1 Drinking Water Monitoring

Six wells on the NNSS are permitted to supply the potable water needs of NNSS operations. These are grouped into three PWSs (Figure 5-4). The largest system (Areas 23 and 6) is classified under its permit as a non-transient, non-community PWS, which serves the main work areas of the NNSS. The other two systems (Area 12 and Area 25) are classified as transient non-community PWSs. The PWSs are designed, operated, and maintained in accordance with the requirements in NAC 445A under permits issued by the NDEP Bureau of Safe Drinking Water (BSDW). PWS permits are renewed annually.

The three PWSs must meet National Primary Drinking Water Standards and Secondary Standards (set by Nevada) for water quality. They are sampled according to a 9-year monitoring cycle, which identifies the specific classes of contaminants to monitor for each drinking water source and the frequency of their monitoring (Table 5-6). At all building locations, the sampling point for coliform bacteria is a sink within the building. Samples for the chemical contaminants are collected at the points of entry to the PWSs. Although not required by regulation or by any permit, the private water systems are monitored quarterly for coliform bacteria to ensure safe drinking water.

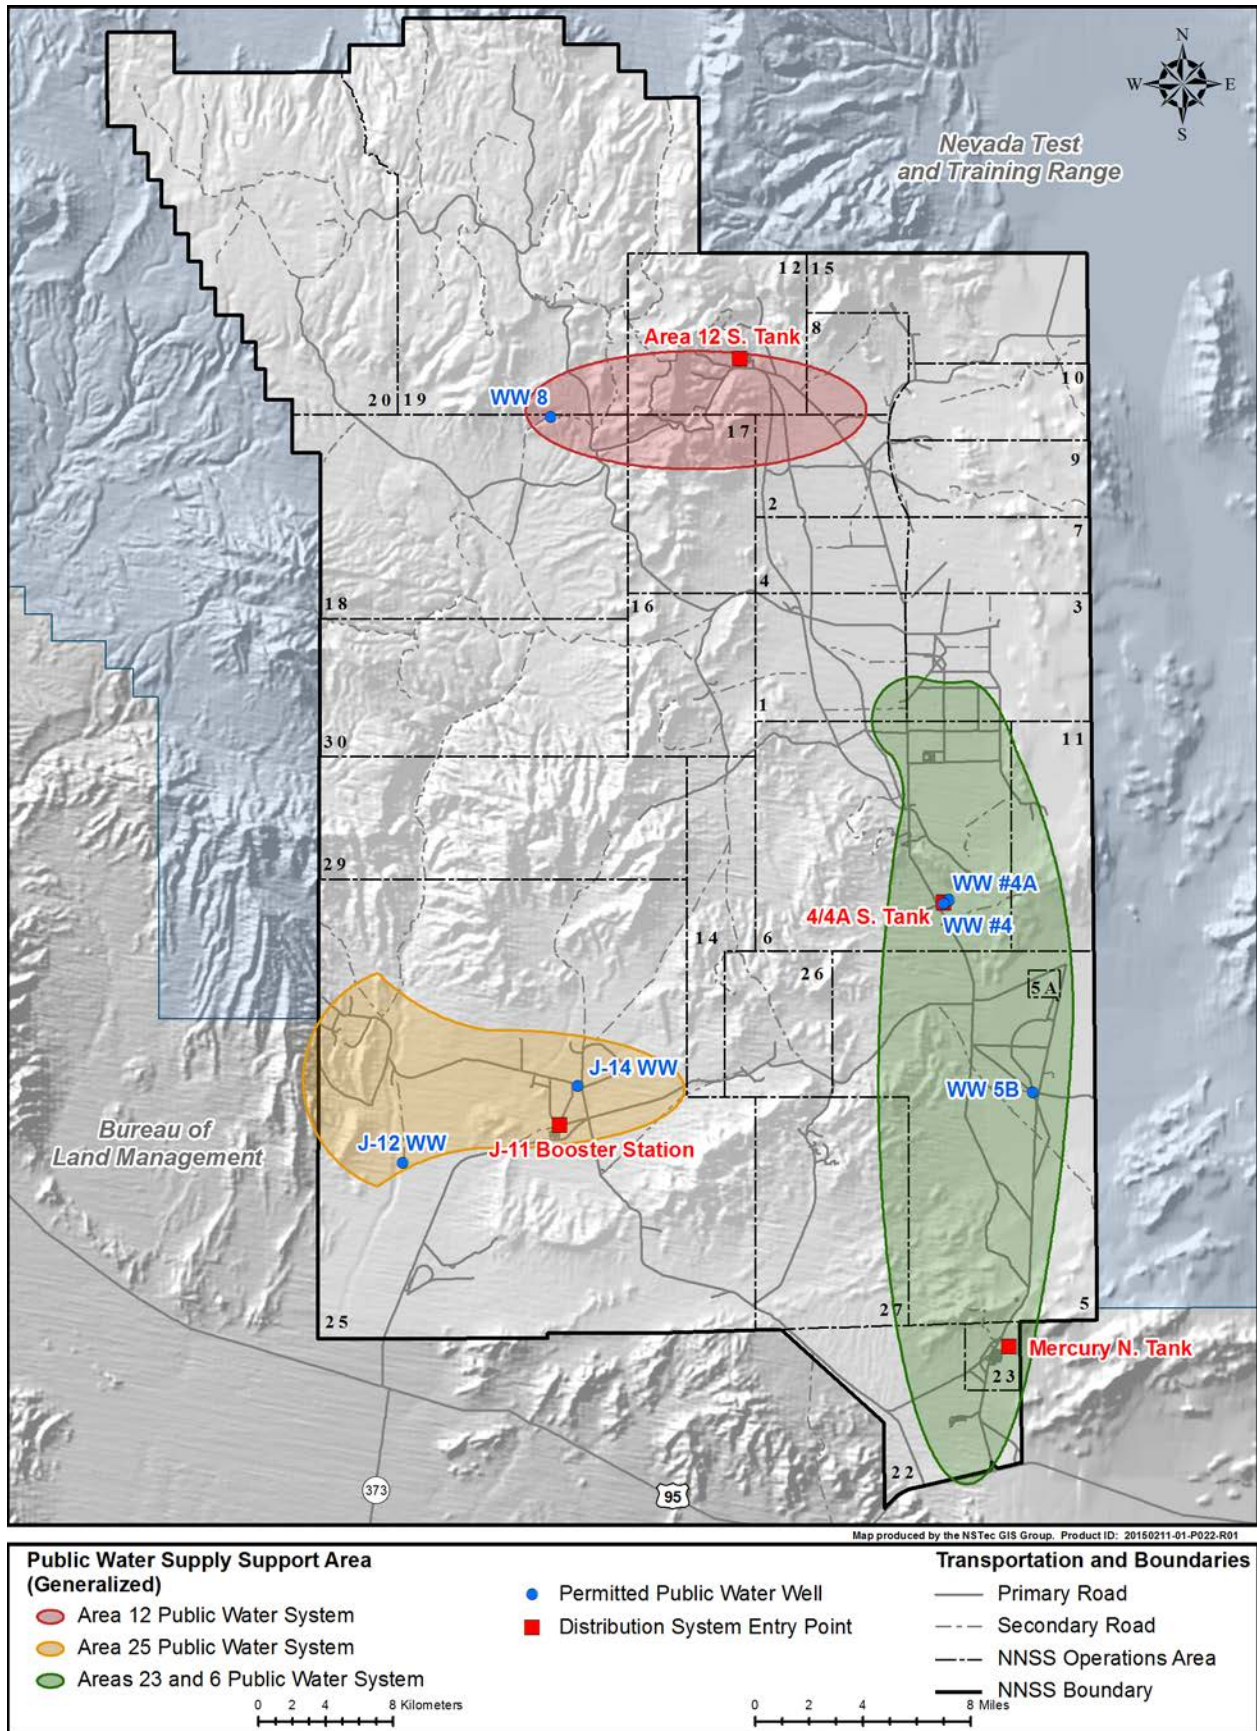

Figure 5-4. Water supply wells and drinking water systems on the NNSS

For work locations at the NNSS that are not part of a PWS, NNSA/NFO hauls potable water in two water tanker trucks. The trucks are permitted by the BSDW to haul water to a PWS, and the water they carry is subject to water quality standards for coliform bacteria (Table 5-6). Normal use of these trucks, however, involves hauling to private water systems (see Glossary, Appendix B) and to hand-washing stations at construction sites, activities not subject to permitting. NNSA/NFO renews the permits for these trucks annually, however.

Table 5-6. Sampling requirements for permitted NNSS PWSs and water-hauling trucks

System/ Truck	Contaminant or Contaminant Category	Sample Location	Sampling Cycle	Number of Samples
Area 23 and 6	National Primary Standards			
	Coliform	WDP-23/6 ^(a)	monthly	2
	Asbestos	WDP-23/6	9 year	1
	Disinfection By-products	WDP-23/6	3 year	3
	Lead and copper	WDP-23/6	3 year	10
	Arsenic	POE-23/6 ^(b)	3 year	1
	IOCs ^(c) - Phase 2 and 5 ^(d)	POE-23/6	9 year	1
	Nitrate	POE-23/6	1 year	1
	Nitrite	POE-23/6	3 year	1
	SOCs ^(e) - Phase 2 and 5	POE-23/6	6 year	1
	VOCs ^(f) - Phase 2 and 5	POE-23/6	3 year	1
	Xylenes	Mercury N. Tank only	1 year	1
	Secondary Standards			
	Secondary IOCs	POE-23/6	3 year	1
Area 12 and Area 25	National Primary Standards			
	Coliform	WDP-12/25 ^(g)	quarterly	1
	Nitrate	POE-12/25 ^(h)	1 year	1
	Nitrite	POE-12/25	3 year	1
	Secondary Standards			
Secondary IOCs	POE-12/25	3 year	1	
Water-Hauling Trucks				
Trucks 84846 and 84847	Coliform Bacteria	Truck valve	monthly	1

(a) WDP-23/6 = Water delivery points for the Area 23 and 6 PWS: taps within Buildings 5-7, 6-609, 6-900, 22-1, 23-180, 23-701, 23-777, 23-1103, and the UIH restroom

(b) POE-23/6 = Points of entry for the Area 23 and 6 PWS: Mercury N. Tank and 4/4A S. Tank (Figure 5-4)

(c) IOCs = Inorganic chemicals

(d) Refers to sets of chemical contaminants in drinking water for which the EPA established maximum contaminant levels (MCLs) through a series of rules known as the Chemical Phase Rules issued from 1987 (Phase 1) through 1992 (Phase 5); see <http://water.epa.gov/lawsregs/rulesregs/sdwa/chemicalcontaminantrules/basicinformation.cfm>.

(e) SOCs = Synthetic organic chemicals

(f) VOCs = Volatile organic chemicals

(g) WDP-12/25 = Water delivery points for the Area 12 and Area 25 PWSs: Buildings 12-909 and 25-3123 or 25-4222

(h) POE-12/25 = Points of entry for the Area 12 and Area 25 PWSs: Area 12 S. Tank, J-11 Booster Station, and J-14 WW (Figure 5-4)

5.2.1.1 2014 Results of PWS and Water-Hauling Truck Monitoring

All 2014 water samples were collected in accordance with accepted practices, and the analyses were performed by State-approved laboratories. The laboratories used approved analytical methods listed in NAC 445A and Title 40 Code of Federal Regulations (CFR) Part 141, "National Primary Drinking Water Standards." The 2014 monitoring results indicated that all of the PWSs complied with National Primary Drinking Water Quality Standards (Table 5-7). Two of the systems complied with Nevada's Secondary Standards for all contaminants,

while the Area 25 system exceeded the secondary standards for aluminum and iron (Table 5-7). The Area 25 PWS users were notified, and additional quarterly water quality monitoring was initiated, as required. The aluminum concentration declined to within the compliance standard in the first quarter of 2015, although iron levels did not. NDEP will determine additional actions should the quarterly iron concentrations continue to exceed the standard. Ingesting iron from drinking water is not directly associated with adverse health effects but with aesthetic effects, such as undesirable taste and odor and staining of clothes and fixtures, and with physical effects such as damage to water equipment and reducing the effectiveness of water treatment for other contaminants.

All water samples from the water-hauling trucks were negative for coliform bacteria in 2014.

Table 5-7. Water quality analysis results for NNSS PWSs

Contaminant	Maximum Contaminant Level	2014 Results		
		Area 23 and 6 PWS	Area 12 PWS	Area 25 PWS ^(a)
National Primary Standards		Milligrams per liter (mg/L)		
Coliform Bacteria	Coliforms present in 1 sample/month	Absent in all samples	Absent in all samples	Absent in all samples
Arsenic	10	9.12 and 7.69	NR ^(b)	NR
Nitrate	10 (as nitrogen)	3.05 and 4.17	1.12	1.94 and 0.88
Nitrite	1 (as nitrogen)	0.10 and 0.10	NS ^(c)	0.09
Secondary Standards				
Aluminum	0.2	NS	ND ^(d)	0.38
Chloride	400	NS	8.78	9.96

(b) NR = Not required under permit to be sampled for transient non-community PWSs

(c) NS = Not scheduled to be sampled in 2014

(d) ND = Not detected in sample

(e) Standard units for measuring pH

5.2.1.2 State Inspections

Periodically, NDEP conducts a sanitary survey of the permitted NNSS PWSs. It consists of an inspection of the wells, tanks, and other visible portions of each PWS to ensure that they are maintained in a sanitary configuration. As non-community water systems, the minimum survey frequency is once every 5 years. In 2014, NDEP conducted a sanitary survey of the PWSs. No deficiencies were noted.

NDEP inspects the two water-hauling trucks annually at the time of permit renewal to make sure they still meet the requirements of NAC 445A. Inspections were performed in June 2014, and permits were renewed.

5.2.2 Domestic Wastewater Monitoring

A total of 23 permitted septic systems for domestic wastewater exist on the NNSS (see Table 2-13 of Chapter 2), and 17 of them were active in 2014 (Figure 5-5). These septic systems are permitted to handle up to 5,000 gallons of wastewater per day. Of the 23 permitted systems, 7 systems are under the direct control of the Solid Waste Department; the remaining 16 systems fall under the supervision and management of the buildings' facility manager. The permitted septic systems are inspected periodically for sediment loading and are pumped as required. The NNSS Management and Operations contractor maintains a septic pumping contractor permit issued by the State. The State conducts onsite inspections of pumper trucks and pumping contractor operations. NNSS personnel perform management assessments of the permitted systems and services to determine and document adherence to permit conditions. The assessments are performed according to existing directives and procedures.

In 2014, there were no compliance actions relating to domestic wastewater on the NNSS.

A septic tank pumping contractor permit (NY-17-03318), four septic tank pump truck permits (NY-17-03313, NY-17-03315, NY-17-03317, NY-17-06838), and a septic tanker permit (NY-17-06839) were approved by the State and renewed in July 2014.

5.2.3 Industrial Wastewater Monitoring

Industrial discharges on the NNSS are limited to three operating sewage lagoon systems: Area 6 Yucca Lake, Area 6 DAF, and Area 23 Mercury (these lagoon systems also receive domestic wastewater) (Figure 5-5). The Area 6 Yucca Lake system consists of two primary lagoons and two secondary lagoons. The DAF system consists of one primary and one secondary lagoon, which were reactivated in 2014 after it was determined that the permitted DAF septic system could not adequately manage the wastewater. The Area 6 Yucca Lake and DAF lagoons are all lined with compacted native soils that meet the State of Nevada requirements for transmissivity (10^{-7} centimeters per second). The Area 23 Mercury system consists of one primary lagoon, a secondary lagoon, and an infiltration basin. The primary and secondary lagoons have a geosynthetic clay liner and a high-density polyethylene liner. The lining of the ponds allows these systems to operate as fully contained, evaporative, non-discharging systems.

5.2.3.1 Quarterly and Annual Influent Monitoring

Sewage systems are monitored quarterly for influent quality. Composite samples from each system are collected over a period of 8 hours and in accordance with accepted practices. The analyses are performed by State-approved laboratories. The laboratories used approved analytical methods listed in NAC 445A and 40 CFR 141. The composite samples are analyzed for three parameters: 5-day biological oxygen demand (BOD_5) (see Glossary, Appendix B), total suspended solids (TSS), and pH. In 2014, all results for BOD_5 , TSS, and pH for sewage system influent waters were within the limits established under Water Pollution Control General Permit GNEV93001 (Table 5-8). Quarterly monitoring reports of these results were submitted to NDEP in April, July, and October 2014 and in January 2015.

The flow is also monitored continuously in the three sewage systems. The Area 6 Yucca Lake and Area 23 Mercury systems operated within the flow limits set in the permit, but the Area 6 DAF system exceeded the flow limit (Table 5-8). The exceedance appears to be the result of discharging clear water from process equipment and/or fire protection systems. NDEP considers the exceedance as a maintenance issue, which is being investigated.

Toxicity monitoring of influent waters of the lagoons was not conducted in 2014. The permit requires that the lagoons be sampled and analyzed for the 29 contaminants shown in Table 4-10 of the *Nevada Test Site Environmental Report 2008* (NSTec 2009) only in the event of specific or accidental discharges of potential contaminants. There were no such discharges that warranted sampling in 2014.

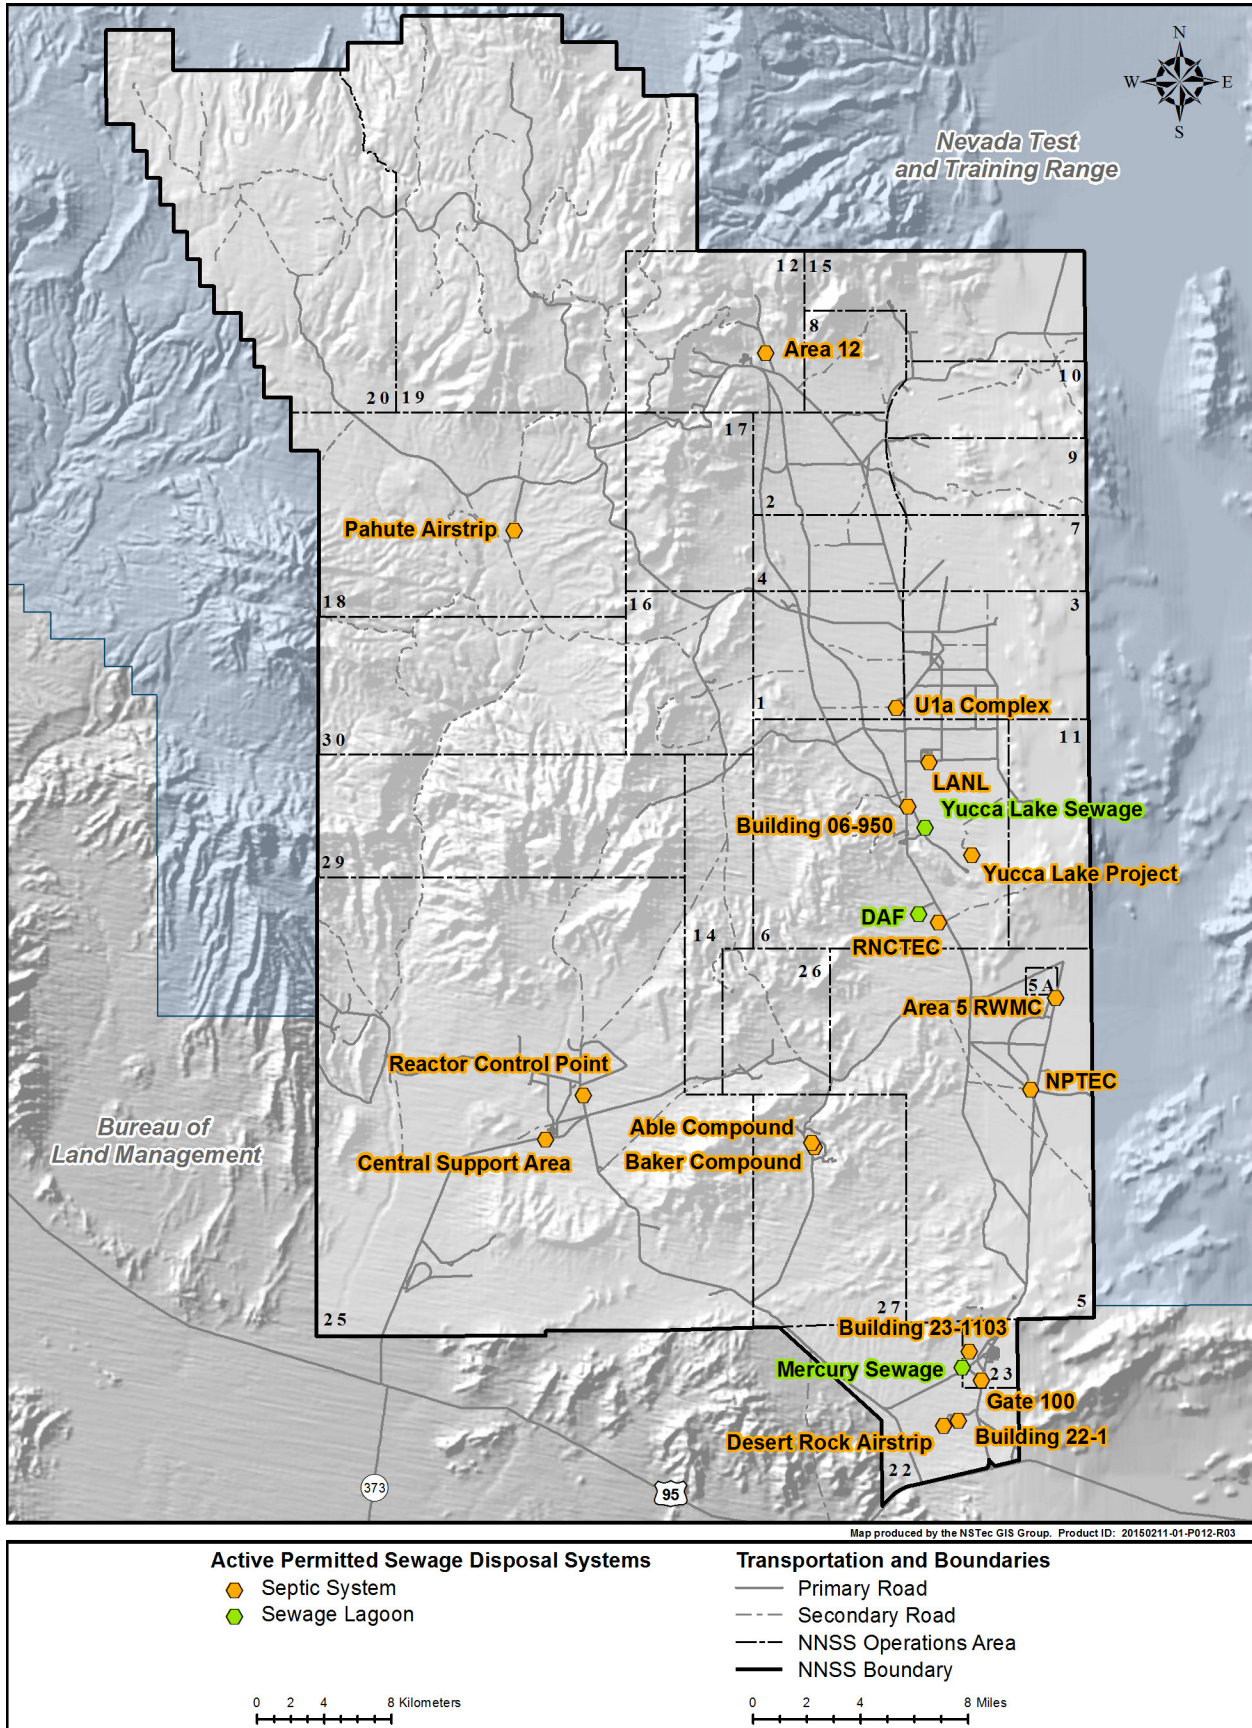

Figure 5-5. Active permitted sewage disposal systems on the NNS

Table 5-8. Water quality analysis and flow monitoring results for NNSS sewage lagoon influent waters in 2014

Parameter	Units	Minimum and Maximum Values from Quarterly Samples		
		Area 6 Yucca Lake	Area 23 Mercury	Area 6 DAF ^(a)
BOD ₅	mg/L	180–400	67–390	59–240
Permit Limit		None	None	None
BOD ₅ Mean Daily Load ^(b)	kg/d	0.222–3.03	5.83–29.55	1.38–7.72
Permit Limit		34.43	124.31	15.29
TSS	mg/L	69–350	59–230	17–220
Permit Limit		None	None	None
pH	S.U. ^(c)	8.12–8.68	7.89–8.48	8.48–8.58
Permit Limit		6.0–9.0	6.0–9.0	6.0–9.0

Permit Limit		10,850	73,407	3,080

(a) Lagoon activated in 3rd quarter; only two quarters of data are represented

(b) BOD₅ Mean Daily Load in kilograms per day (kg/d) = (mg/L BOD × liters per day (L/d) average flow × 3.785)/10⁶

(c) Standard units of pH

(d) Gallons per day

5.2.3.2 Sewage System Inspections

NNSS personnel inspect active systems weekly and inactive lagoon systems quarterly. NDEP inspects both active and inactive NNSS lagoon systems annually. NNSS personnel inspect for abnormal conditions, weeds, algae blooms, pond color, abnormal odors, dike erosion, burrowing animals, discharge from ponds or lagoons, depth of staff gauge, crest level, excess insect population, maintenance/repairs needed, and general conditions. NNSS personnel conducted weekly and quarterly inspections throughout the year. They cover field maintenance programs, lagoons, sites, and access roads functional to operations. There were no notable findings from the onsite inspections. NDEP performed an annual inspection in 2014, and there were no findings.

5.2.4 ETDS Monitoring

NNSA/NFO manages and operates the ETDS in Area 12 under a separate water pollution control permit (NEV 96021) issued by the NDEP Bureau of Federal Facilities. The permit governs the management of radionuclide-contaminated wastewater that drains from the E Tunnel portal into a series of holding ponds. The permit requires ETDS discharge waters to be monitored every 12 months for radiological parameters (see Table 5-5 and Section 5.1.3.7.2) and for the nonradiological parameters listed in Table 5-9. It also requires nearby Well ER-12-1 to be sampled for the same parameters but at a frequency of once every 24 months. The ETDS is also monitored monthly for flow rate, pH, temperature, and specific conductance (SC) of the discharge water and the total volume and structural integrity of the holding ponds. Monitoring data are reported to the NDEP Bureau of Federal Facilities in annual and quarterly reports. On October 14, 2014, monitoring personnel sampled the ETDS discharge water, and all nonradiological parameters were within the threshold limits specified by the permit (Table 5-9).

Table 5-9. Nonradiological results for ETDS discharge samples collected in 2014

Contaminant	Threshold Limit (mg/L)	Measured Value (mg/L)
Cadmium	0.045	0.0002
Chloride	360	0.0007
Chromium	0.09	9.6
Copper	1.2	0.002
Fluoride	3.6	0.18
Iron	5.0	1.9
Lead	0.014	0.001
Magnesium	135	1

Table 5-9. Nonradiological results for ETDS discharge samples collected in 2014 (continued)

	Threshold Limit (mg/L)	Measured Value (mg/L)
Manganese	0.25	0.02
Mercury	0.0018	0.00006
Nitrate nitrogen	9	0.34
Selenium	0.045	0.0007
Sulfate	450	16
Zinc	4.5	0.04

5.2.5 Environmental Impact

Drinking water and wastewater parameters monitored in 2014 were within permit limits, with the following exceptions: Area 25 PWS exceeded the Nevada Secondary Standards for aluminum and iron, and the DAF sewage lagoon exceeded the daily flow limit. The Area 25 exceedances were determined to have been due to natural causes or the condition of the water distribution systems themselves; they have not been the result of the release of contaminants into the groundwater from site operations. The DAF sewage lagoon flow exceedance had no impact, as there was no loss of containment. If present, nonradiological contamination of groundwater from NNS operations would likely be co-located with the radiological contamination that has occurred from historical underground nuclear testing within UGTA CAUs. It is expected to be minor, however, in comparison to the radiological contamination. For nuclear tests above the water table, potential nonradiological contaminants are not likely to reach groundwater because of their negligible advective and dispersive transport rates through the thick vadose zone. Water samples from UGTA investigation wells, which include highly contaminated wells, have not had elevated levels of nonradiological man-made contaminants.

Well drilling, waste burial, chemical storage, and wastewater management are the only current NNS activities that have the potential to contaminate groundwater with nonradiological contaminants. This potential is very low, however, due to engineered and operational deterrents and natural environmental factors. Current drilling operations procedures include the containment of drilling muds and well effluents in sumps (see Section 5.1.3.7.3). Well effluents are monitored for nonradiological contaminants (predominantly lead) to ensure that lined sumps are used when necessary. The Area 3 and Area 5 Radioactive Waste Management Sites and the solid waste landfills are designed and monitored to ensure that contaminants do not reach groundwater (see Chapter 10). In addition, the potential for mobilization of contaminants from all these sources to groundwater is negligible due to the arid climate, the extensive depth to groundwater (thickness of the vadose zone), and the proven behavior of liquid and vapor fluxes in the vadose zone (primarily upward liquid movement towards the ground surface).

The Environmental Restoration program, for the Soils and Industrial Sites, conducts cleanup and closures of historical surface and shallow subsurface contamination sites, some of which have nonradiological contaminants like metals, petroleum hydrocarbons, hazardous organic and inorganic chemicals, and unexploded ordnance (see Sections 11.2 and 11.3). The potential for mobilization of these contaminants to groundwater is negligible due to the same regional climatic, soil, and hydrogeologic factors mentioned above.

No past or present NNSA/NFO operations are known to have contaminated natural springs or ephemeral surface waters on the NNS.

Chapter 6: Direct Radiation Monitoring

Ronald W. Warren

National Security Technologies, LLC

Charles B. Davis

EnviroStat

U.S. Department of Energy (DOE) Orders DOE O 458.1, “Radiation Protection of the Public and the Environment,” and DOE O 435.1, “Radioactive Waste Management,” have requirements to protect the public and environment from exposure to radiation (see Chapter 2, Section 2.4). Energy absorbed from radioactive materials outside of the body results in an external dose. External dose comes from direct ionizing radiation on the Nevada National Security Site (NNSS), including natural radioactivity from cosmic and terrestrial sources as well as man-made radioactive sources. This chapter presents the data obtained to assess external dose during 2014. Chapters 4, 5, and 8 present the monitoring results of radioactivity from NNSS activities in air, water, and biota, respectively. Those results are used to estimate potential internal radiation dose to the public via inhalation and ingestion. The total estimated dose, both internal and external, from NNSS activities is presented in Chapter 9.

Direct radiation monitoring is conducted to assess the external radiation environment, detect changes in that environment, respond to releases from U.S. Department of Energy, National Nuclear Security Administration Nevada Field Office (NNSA/NFO) activities, and measure gamma radiation levels near potential exposure sites. In addition, DOE O 458.1 states that “it is also an objective that potential exposures to members of the public be as low as is reasonably achievable (ALARA).”

Direct Radiation Monitoring Program Goals

Assess the proportion of external dose that comes from background radiation versus NNSS operations.

Measure external radiation in order to assess the potential external dose to a member of the public from all NNSA/NFO operations at the NNSS and determine if the total dose (internal and external) complies with the 100 millirem per year (mrem/yr) (1 millisievert [mSv]/yr) dose limit of DOE O 458.1 (see Chapter 9 for estimates of public dose).

Measure external radiation in order to assess the potential external dose to a member of the public from operations at the Area 3 and Area 5 Radioactive Waste Management Sites (RWMSs) and determine if the total dose complies with the 25 mrem/yr (0.25 mSv/yr) dose limit to members of the public specified in DOE Manual DOE M 435.1-1, “Radioactive Waste Management Manual” (see Chapter 9 for estimates of public dose).

Monitor operational activities involving radioactive material, radiation-generating devices, and accidental releases of radioactive material to ensure exposure to members of the public are kept ALARA as stated in DOE O 458.1.

Determine if the absorbed radiation dose (in a unit of measure called a rad [see Glossary, Appendix B]) from external radiation exposure to NNSS terrestrial plants and aquatic animals is less than 1 rad per day (1 rad/d) (0.01 gray/d), and if the absorbed radiation dose to NNSS terrestrial animals is less than 0.1 rad/d (1 milligray/d) (limits prescribed by DOE O 458.1 and DOE Standard DOE-STD-1153-2002, “A Graded Approach for Evaluating Radiation Doses to Aquatic and Terrestrial Biota”) (see Chapter 9, Section 9.2 for biota dose assessments).

Determine the patterns of exposure rates through time at various soil contamination areas in order to characterize releases in the environment.

An offsite monitoring program has been established by NNSA/NFO to monitor direct radiation in communities adjacent to the NNSS. The Desert Research Institute (DRI) conducts this monitoring as part of its Community Environmental Monitoring Program (CEMP). DRI’s 2014 direct radiation monitoring results are presented in Chapter 7, Sections 7.1.2 and 7.1.3, and are compared with those from onsite thermoluminescent dosimeters (TLDs) in this chapter (see Figures 6-2 and 6-3).

6.1 Measurement of Direct Radiation

Direct (or external) radiation exposure can occur when alpha particles, beta particles, or electromagnetic (gamma and X-ray) radiation interact with living tissue. Electromagnetic radiation can travel long distances through air and penetrate living tissue, causing ionization within the body tissues. For this reason, electromagnetic radiation is one of the greater concerns of direct radiation exposure. By contrast, alpha and beta particles do not travel far in air (a few centimeters for alpha, and about 10 meters [m] or 33 feet [ft] for beta particles). Alpha particles deposit only negligible energy to living tissue as they rarely penetrate the outer dead layer of skin and cannot penetrate thin plastic. Beta particles are generally absorbed in the layers of skin immediately below the outer layer.

Direct radiation exposure is usually reported in the unit milliroentgen (mR), which is a measure of exposure in terms of numbers of ionizations in air. The dose in human tissue resulting from an exposure from the most common radionuclides can be approximated by equating a 1 mR exposure with a 1 mrem (0.01 mSv) dose.

6.2 Thermoluminescent Dosimetry Surveillance Network Design

A surveillance network of TLD sampling locations has been established on the NNSS to monitor those NNSS areas that have elevated radiation levels resulting from historical nuclear weapons testing, current and past radioactive waste management activities, and/or current operations involving radioactive material or radiation-generating devices. The objectives and design of the network are described in detail in the *Routine Radiological Environmental Monitoring Plan (RREMP)* (Bechtel Nevada 2003).

TLDs have the capability to measure exposure from all sources of ionizing radiation, but with normal use the TLD will detect only electromagnetic radiation, high-energy beta particles, and in some special cases neutrons. This is due to the penetrative abilities of the radiation. The TLD currently used for environmental sampling is the Panasonic UD-814AS, which has three calcium sulfate elements housed in an air-tight, water-tight, ultra-violet light-protected case. Measurements from the three calcium sulfate elements are averaged to assess penetrating gamma radiation.

A pair of TLDs is placed at 1.0 ± 0.3 m (28 to 51 inches [in.]) above the ground at each monitoring location. These are exchanged quarterly for analysis. Analysis of TLDs is performed using automated TLD readers calibrated and maintained by the Radiological Control Department. Reference TLDs are exposed to a 100 mR cesium-137 source under tightly controlled conditions. These are read along with TLDs collected from the network to calibrate their responses.

There were 104 active environmental TLD locations on the NNSS (Figure 6-1) during 2014 plus six control locations. They include the following numbers and types:

- Background (B) – 11 locations where radiation effects from NNSS operations are negligible. In Area 5, one location (3.3 Miles SE of Aggregate Pit) was decommissioned after the third quarter, and a new location (Old Indian Springs Road) was established in the second quarter.
- Environmental 1 (E1) – 41 locations where there is no measurable radioactivity from past operations, but are locations of interest due to the presence of people in the area and/or the potential for increased radiation exposure from a current operation.
- Environmental 2 (E2) – 35 locations where there is measurable added radioactivity from past operations; these locations are of interest for monitoring direct radiation trends in the area. Some locations fitting this description are grouped with the Waste Operations category below.
- Waste Operations (WO) – 17 locations in and around the Area 3 and Area 5 RWMSs.
- Control (C) – 5 locations in Building 652 and 1 location in Building 650 (both in Area 23). Control TLDs are kept in stable environments. Those in Building 652 are shielded inside a lead cabinet, and those in Building 650 are shielded by just the building itself. These TLDs are used as a quality check on the TLDs and the analysis process.

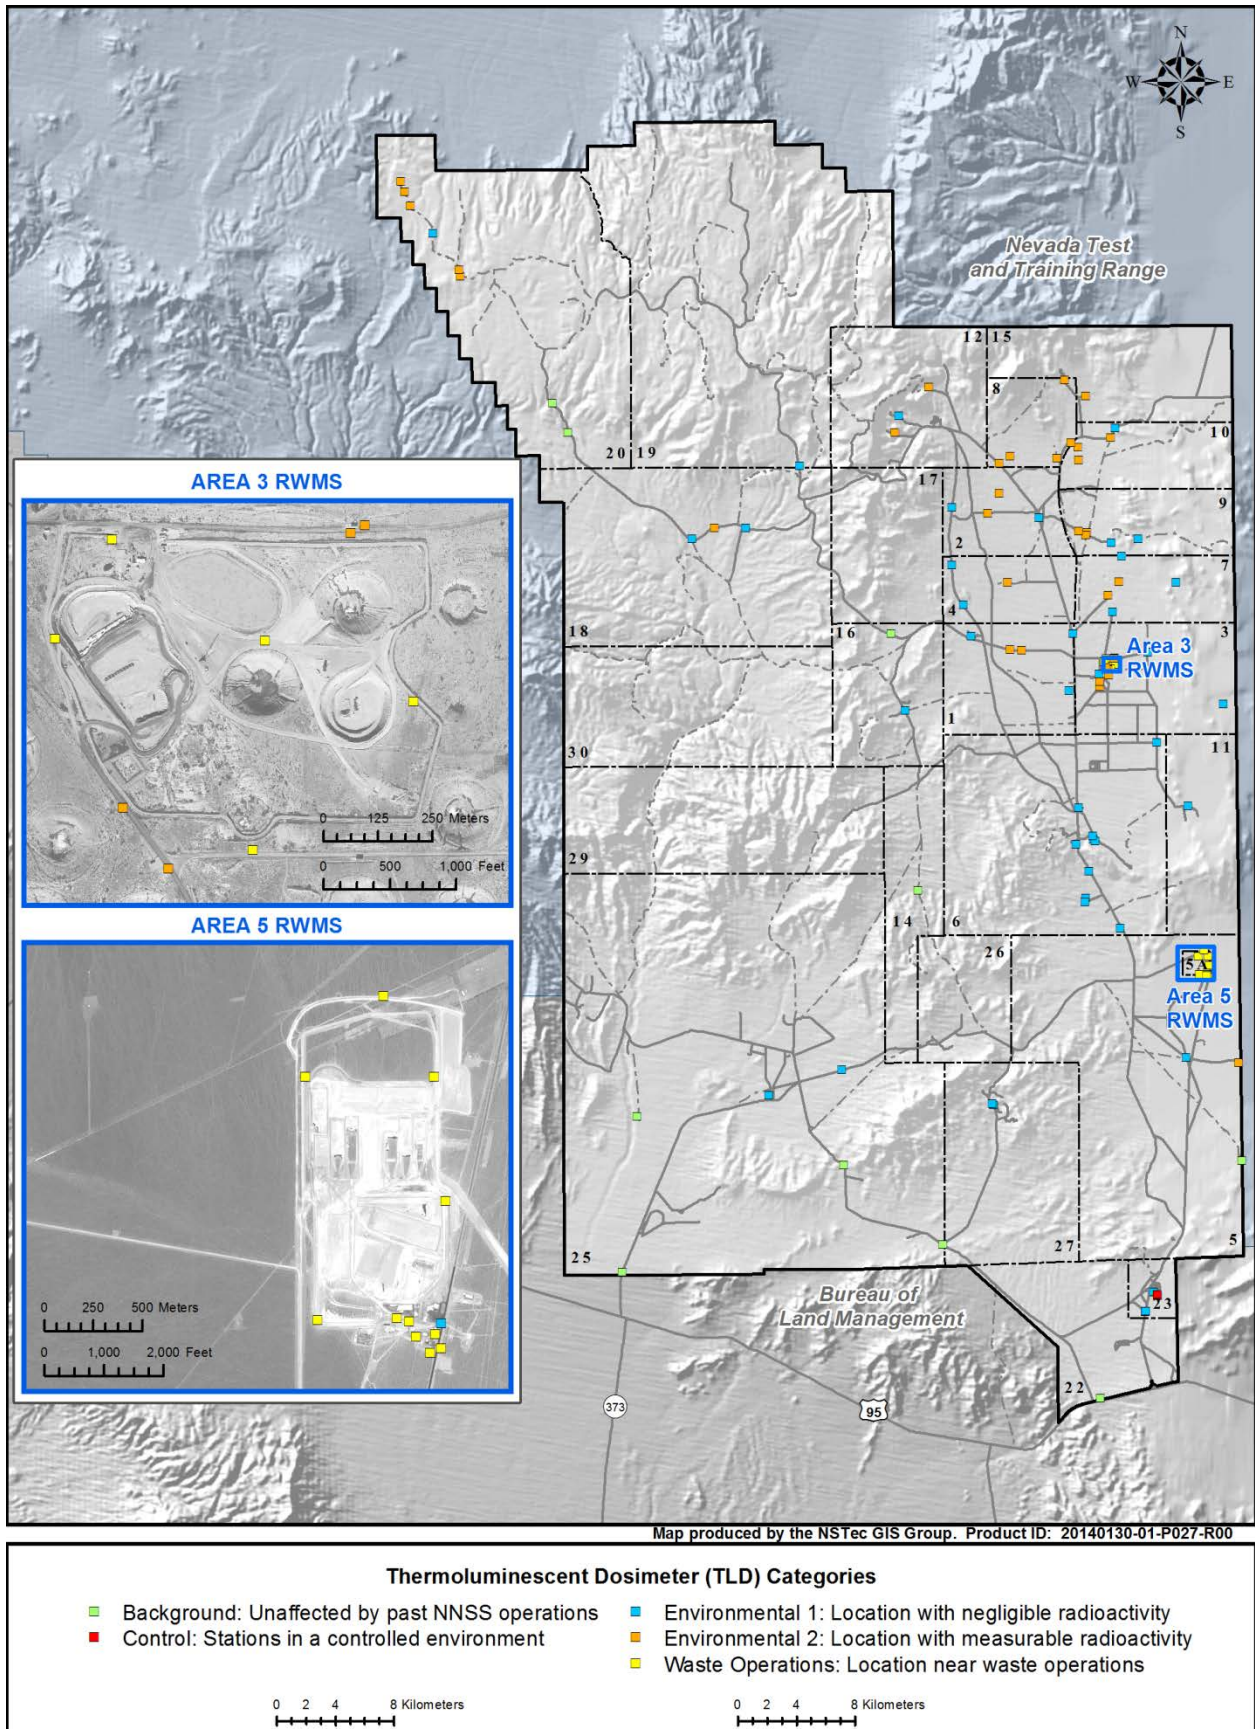

Figure 6-1. Location of TLDs on the NNSS

6.2.1 Data Quality

Quality assurance (QA) procedures for direct radiation monitoring involve comparing the data from the paired TLDs at each location to estimate the measurement and its precision, comparing current and past data measurements at each TLD location, and reviewing data from the TLDs in the control locations. The TLDs in control locations allow the detection and estimation of any systematic variations that might be introduced by the measurement process itself.

As directed by the RREMP, QA and quality control (QC) protocols (including Data Quality Objectives) have been developed and are maintained as essential elements of direct radiation monitoring. The QA/QC requirements established for the monitoring program include the use of sample packages to thoroughly document each sampling event, rigorous management of databases, and completion of essential training (see Chapter 16). The Radiological Control Department maintains certification through the U.S. Department of Energy Laboratory Accreditation Program for dosimetry.

There are four consecutive steps in the monitoring process for each environmental TLD: the TLD is (1) annealed (i.e., heated and then cooled) to reset it to its original unexposed condition, and stored in a shielded location; (2) deployed to the field at the beginning of the quarter; (3) collected from the field at the end of the quarter; and (4) again stored in a shielded location until it is read. In the past, perturbations have been noticed in the data related to the variability in the amount of time TLDs were held in shielded locations prior to deployment and following collection. An adjustment procedure was developed and implemented in 2014 to control for the variability in this additional dose. It involves estimating the additional dose based on the holding time and the shielded control location measurements, and subtracting that estimate from the measured dose before computing annual exposure estimates. With the 2014 data, this adjustment in nearly all cases, resulted in a decrease in estimated dose of between 1% and 5%; the adjustment was larger for one TLD pair with an atypically long holding time. This adjustment has been applied retroactively to data from 2003 on.

6.2.2 Data Reporting

Direct radiation is recorded as exposure per unit time in milliroentgens per day (mR/d), calculated by dividing the measured exposure per quarter for each TLD by the number of days the TLD was exposed at its measurement location. These are multiplied by 365.25 to obtain annualized values. The estimated annual exposure is the average of the quarterly annualized values; this is the metric used to determine compliance with federal annual dose limits.

6.3 Results

Estimated annual exposures for all TLD locations are given in Table 6-1. Summary statistics for the five location types are given in Table 6-2 and Figure 6-2. Data were successfully obtained from nearly all of the TLDs during all quarters of 2014. The measurement from one TLD during one quarter was rejected due to inadequate inter-element agreement. Otherwise, agreement between the results provided by the paired TLDs was quite good, with an average relative percent difference between measurements of 3.0%. The quarter-to-quarter coefficient of variation (CV) (i.e., the relative standard deviation) ranged from 0.4% to 6.1% (median = 2.8%) over all locations excluding the Gate 100 Truck Parking 1 location (see the discussion in Section 6.3.2).

6.3.1 Background Exposure

During 2014, the average of the estimated annual exposures among the 11 background locations was 114 mR, ranging from 65 to 163 mR (Table 6-2). A 95% prediction interval (PI) for annual exposures based on the 2014 estimated mean annual exposures at the background locations (denoted “95% PI from B” in the plots) is 35.9 to 192.6 mR. This interval predicts mean annual background exposures at locations where radiation effects from NNSS operations are negligible.

For comparison, the CEMP’s estimated annual exposure in Las Vegas, Nevada (at 617 m [2,025 ft] elevation), was 109 mR during 2014 (see Chapter 7, Table 7-3). Estimated annual exposures at CEMP locations ranged from 87 mR at St. George, Utah (752 m [2,600 ft] elevation), to 147 mR at Beatty, Nevada (930 m [3,216 ft] elevation).

There is a general increasing relationship between natural background exposure and elevation (Figure 6-3), generally due to cosmic radiation. The NNSS background locations with lowest and highest exposures are at elevations 1,087 m (3,568 ft) at Area 5, 3.3 miles (mi) southeast (SE) of Aggregate Pit; and 1,737 m (5,700 ft) at Area 20, Stake A-112, respectively

Exposure estimates at all locations include contributions from natural sources. It is important to note that the DOE dose limits to the public are for dose over and above what may be received from natural sources.

(a) To obtain daily exposure rates, divide annual exposure measures by 365.25.

(b) Location types:

B: Background locations

C: Control locations

E1: Environmental locations with exposure rates near background but monitored for potential for increased exposure rates due to NNSS operations

E2: Environmental locations with measurable radioactivity from past operations, excluding those designated WO

WO: Locations in or near waste operations

(c) Mean, minimum, and maximum values from adjusted quarterly estimates. Each quarterly estimate is the average of two TLD readings per location.

Table 6-2. Summary statistics for 2014 mean annual direct radiation exposures by TLD location type

Location Type	Number of Locations	Estimated Annual Exposure (mR)		
		Mean	Minimum	Maximum
Background (B)	11	114	65	163
Environmental 1 (E1)	41	114	57	161
Environmental 2 (E2)	35	219	96	538
Waste Operations (WO)	17	135	99	292
Control, Shielded (C)	5	25	24	25
Control, Unshielded (C)	1	57	55	58

Figure 6-3. Correlation between 2014 annual exposures at NNSS Background and CEMP TLD locations and altitude

6.3.2 Potential Exposure to the Public along the NNSS Boundary

Most of the NNSS is not accessible to the public; the public has limited access only at the southern portion of the NNSS. Gate 100 is the primary entrance point to the NNSS. The outer parking areas are accessible to the public. Trucks hauling radioactive materials, primarily low-level waste (LLW) destined for disposal in the RWMSs, often park outside Gate 100 while waiting to enter the NNSS. Two TLD locations were established in October 2003 to monitor this truck parking area.

The TLDs at the north end of the parking area (Gate 100 Truck Parking 2) had an estimated annual exposure of 61 mR during 2014, with quarterly estimates of 58, 59, 63, and 61 mR. The TLD location about 64 m away, on the west side of the parking area (Gate 100 Truck Parking 1), has had elevated exposure levels at various times in its history, likely due to exposure to waste shipments. Its average value for 2014 was 85 mR, with quarterly estimates of 108, 86, 68, and 78 mR. All results for both truck parking locations are within the range of background variation; however, most quarterly exposure estimates are higher than those at the nearby Mercury Fitness Track station, likely due to exposure to waste shipments.

While the public has limited access to the NNSS at Gate 100 along its southern border, others may have access to other boundaries of the NNSS. Most of the NNSS is bounded by the Nevada Test and Training Range (NTTR).

Military or other personnel on the NTTR who are not classified as radiation workers would also be subject to the 100 mrem/yr (1 mSv/yr) public dose limit. Nuclear tests on the NTTR (Double Tracks and Project 57) consisted of experiments where weapons were exploded conventionally without going critical (safety experiments). These areas, therefore, have primarily alpha-emitting radionuclides that do not contribute significantly to external dose. Historical nuclear testing activities also occurred on the Tonopah Test Range (TTR) (Clean Slate I, II, and III) located in the northwest portion of the NTTR. Radiation exposure rates are measured on and around the TTR, and the results are reported by Sandia National Laboratories in the 2014 TTR annual environmental report, which is posted at <http://www.sandia.gov/news/publications/environmental/index.html>.

A radioactive material area boundary extends beyond the NNSS in the Frenchman Lake region of Area 5 along the southeast boundary of the NNSS. This region was a location of atmospheric weapons testing in the 1950s and is inaccessible to the public. A TLD location was established there in July 2003 to characterize direct radiation levels from this legacy soil contaminated area and to assess the external dose to personnel not classified as radiation workers who may visit the area. The estimated annual exposure to a hypothetical person at the Frenchman Lake TLD location during 2014 was 271 mR. This has been consistently declining over time, down from 420 mR in 2003. The resulting estimated above-background dose during 2014 would be approximately 108 to 206 mrem, depending on which background value is subtracted. This would exceed the 100 mrem dose limit to a person residing year-round at this location, but there are no living quarters or full-time non-radiation workers in this vicinity. Workers specially trained and classified as radiation workers, although they do not work in the vicinity, have a higher allowable dose limit of 5,000 mrem per year, which would not be exceeded in the vicinity of the Frenchman Lake TLD.

Based on these results, the potential external dose to a member of the public due to past or present operations at the NNSS does not exceed 100 mrem/yr (1 mSv/yr) and exposures are kept ALARA, as required by DOE O 458.1.

6.3.3 Exposures from NNSS Operational Activities

Forty-one TLDs are in locations where workers, or at some, the public, have the potential to receive radiation exposure from current operations (E1 locations). E1 locations have negligible radioactivity from past operations. The mean estimated annual exposure at these locations was 114 mR during 2014, approximately the same as the mean estimated annual exposure at background locations (see Table 6-2). Overall, annual exposures were not different between B and E1 locations (Figure 6-2); the estimated annual exposures at all E1 locations are well within the 95% PI of B locations. E1 location exposures were also comparable with the offsite exposures reported by the CEMP stations, as shown in Figure 6-2.

6.3.4 Exposures from RWMSs

DOE M 435.1-1 states that LLW disposal facilities shall be operated, maintained, and closed so that a reasonable expectation exists that annual dose to members of the public shall not exceed 25 mrem from all exposure pathways combined. The RWMSs are located well within the NNSS boundaries, which are patrolled by security personnel; no member of the public can access these areas for significant periods of time. However, TLDs placed at the RWMSs show the potential dose from external radiation to a hypothetical person residing year-round at each RWMS.

Between 1952 and 1972, 60 nuclear weapons tests were conducted in Yucca Flat within 400 m (1,312 ft) of the current Area 3 RWMS boundary. Fourteen of these tests were atmospheric tests that left radionuclide-contaminated surface soil and, therefore, elevated radiation exposures across the area. Waste pits in the Area 3 RWMS are subsidence craters from seven subsurface tests, which have been filled with LLW and then covered with clean soil. As a result, exposures inside the Area 3 RWMS are low when compared with those at or outside the fence line.

Annual exposures measured inside the Area 3 RWMS and three of four at the boundary were within the range of NNSS background exposures in 2014 (Figure 6-4). The boundary location A3 RWMS South has an estimated exposure above the range of NNSS background and is 160 m (525 ft) from the site of two atmospheric nuclear weapons tests. The three E2 TLD locations outside the RWMS that are also above the range of NNSS background (Figure 6-4) are a similar distance from the same atmospheric tests, but on the other side, farther from the RWMS boundary. Based on these measurements, it does not appear that waste buried at the Area 3 RWMS would have contributed external exposure to a hypothetical person residing at its boundary during 2014.

Figure 6-4. 2014 annual exposures in and around the Area 3 RWMS and at background locations

The Area 5 RWMS is located in the northern portion of Frenchman Flat. Between 1951 and 1971, 25 nuclear weapons tests were conducted within 6.3 kilometers (km) (3.9 mi) of the Area 5 RWMS. Fifteen of these were atmospheric tests and, of the remaining ten, nine released radioactivity to the surface, which contributes to exposures in the area. No nuclear weapons testing occurred within the boundaries of the Area 5 RWMS.

During 2014, estimated annual exposures at Area 5 RWMS TLD locations were within the range of exposures measured at NNS background locations (Figure 6-5). The one location outside the Area 5 RWMS (Frenchman Lake) that has an estimated exposure above background levels is within 0.5 km (0.3 mi) of six atmospheric tests in Frenchman Lake Playa. Based on these results, the potential external dose to a member of the public from operations at the Area 3 and Area 5 RWMSs does not exceed the 25 mrem/yr (0.25 mSv/yr) dose limit to members of the public, specified in DOE M 435.1-1. See Section 9.1.2 of this report for a summary of the potential dose to the public from the RWMSs from all exposure pathways.

Figure 6-5. 2014 annual exposures around the Area 5 RWMS and at background locations

6.3.5 Exposures to NNSS Plants and Animals

The highest exposure rate measured at any TLD location during 2014 was 558 mR/yr (1.57 mR/d), at the Schooner-1 location during the third quarter (Table 6-1). Given such a large area source, there is very little difference between the exposure measured at a height of 1 m (3.3 ft) and that measured near the ground (e.g., 3 centimeters [1.2 in.]) where small plants and animals reside. The daily exposure rate near the ground surface would be less than 2% of the 0.1 rad/d (approximately 100 mR/d or 36,500 mR/yr) total dose rate limit to terrestrial animals, as stated in DOE-STD-1153-2002. Hence, doses to plants and animals from external radiation exposure at NNSS monitoring locations are very low compared with the dose limit. Dose to biota from both internal and external radionuclides is presented in Chapter 9.

6.3.6 Exposure Patterns in the Environment over Time

Direct radiation monitoring is conducted to help characterize releases from NNSA/NFO activities. Continued monitoring of exposures at locations of past releases on the NNSS helps to accomplish this. Small quarter-to-quarter changes are normally seen in exposure rates from all locations. During 2014, the CVs for measurements between quarters averaged 3.0%. Only the CV for Gate 100 Truck Parking 1 (19.9%) was above 10.0%.

Long-term trends are displayed in Figure 6-6 by location type for locations that have been monitored for at least 10 years. As expected, the B and C locations show virtually no net change through time due to the protected locations and lack of added man-made radionuclides. Among all locations with at least 10-year data histories, the annual exposures at E1 locations decreased an average of 0.38% per year, those at E2 locations decreased 2.01% per year on average, and those at WO locations decreased 0.77% per year on average. Annual exposures decreased 3.21% per year on average at those locations with significant added man-made radiation, those being the E2 and WO locations with 2014 estimated exposures higher than the 95% PI calculated from B locations. These average rates of decay are very similar to those measured from 2008 through 2013. The observed decreases are due to a combination of natural radioactive decay, dispersal, and dilution in the environment.

The two stations with the highest exposures in recent history, Schooner-1 in Area 20 and Stake A-9 in Area 4, are decreasing at a rate of about 50% every 13 and 17 years, respectively, as seen in Figure 6-6.

Figure 6-6. Trends in direct radiation exposure measured at TLD locations

6.4 Environmental Impact

Direct radiation exposure to the public from NNSS operations during 2014 was negligible. Radionuclides historically released to the environment on the NNSS have resulted in localized elevated exposures. These areas of elevated exposure are not open to the public, nor do personnel work in these areas full-time. Overall exposures at the RWMSs appear to be generally lower inside and at the boundary than those outside the RWMSs. This is due to the presence of radionuclides released from historical testing distributed throughout the area around the RWMSs compared with the clean soil used inside the RWMSs to cap waste cells. The external dose to plants and animals at the location with the highest measured exposure was a small fraction of the dose limit to biota; hence, no detrimental effects to biota from external radiation exposure are expected at the NNSS.

Chapter 7: Community Environmental Monitoring Program

Scott A. Campbell, William T. Hartwell, Lynn H. Karr, Charles E. Russell, and Craig Shadel

Desert Research Institute

In addition to the environmental monitoring conducted by the U.S. Department of Energy, National Nuclear Security Administration Nevada Field Office (NNSA/NFO) on the Nevada National Security Site (NNSS) (see Chapters 4, 5, 6, and 8), independent monitoring is provided through the Community Environmental Monitoring Program (CEMP). The CEMP's mission is to provide data to the public which is collected off the NNSS regarding the presence of man-made radionuclides that could be the result of current operations or past nuclear testing on the NNSS. Initially, the CEMP network functioned as a first line of offsite detection of potential radiation releases from underground nuclear tests at the NNSS. It currently exists as a non-regulatory public informational and outreach program. The CEMP is sponsored by the NNSA/NFO, and is administered and operated by the Desert Research Institute (DRI) of the Nevada System of Higher Education.

Monitored and collected data include, but are not necessarily limited to, background and airborne radiation data, meteorological data, and tritium concentrations in community and ranch drinking water. Network air monitoring stations, located in Nevada, Utah, and California, are managed by local citizens, many of them high school science teachers, whose routine tasks are to ensure equipment is operating normally and to collect air filters and route them to the DRI for analysis. These Community Environmental Monitors (CEMs) are also available to discuss the monitoring results with the public and to speak to community and school groups. DRI's responsibilities include maintaining the physical monitoring network through monthly visitations by environmental radiation monitoring specialists, who also participate in training and interfacing with CEMs and interacting with other local community members and organizations to provide information related to the monitoring data. DRI also provides public access to the monitoring data through maintenance of a project website at <http://www.cemp.dri.edu/>. A detailed informational background narrative about the CEMP can be found at <http://www.cemp.dri.edu/cemp/moreinfo.html> along with more detailed descriptions of the various types of sensors found at the stations and on outreach activities conducted by the CEMP.

CEMP Goals

Provide independent monitoring at offsite locations and communicate environmental data relevant to past and continuing activities at the NNSS

Engage the public hands-on in monitoring environmental conditions in their communities relative to activities at the NNSS

Communicate environmental monitoring data to the public in a transparent and accessible manner

Provide an educated, trusted, local resource for public inquiries and concerns regarding past and present activities at the NNSS

7.1 *Offsite Air Monitoring*

In 2014, DRI managed 24 CEMP stations, which compose the Air Surveillance Network (ASN) (Figure 7-1). The ASN stations include various types of equipment used to monitor airborne radiation and meteorological conditions, as described in Section 7.1.1. The CEMP station in Beatty, Nevada, which has all of the air monitoring equipment described in Section 7.1.1, is shown in Figure 7-2.

7.1.1 *Air Monitoring Equipment*

CEMP Low-Volume Air Sampler Network – During 2014, the CEMP ASN included continuously operating low-volume particulate air samplers at 12 “full-time” stations that are either near to, or typically downwind from, the NNSS (Figure 7-1). The ASN in 2014 also included low-volume air samplers at 11 “standby” stations that are either farthest from the NNSS or most frequently upwind from the NNSS; these samplers collected 2-week air

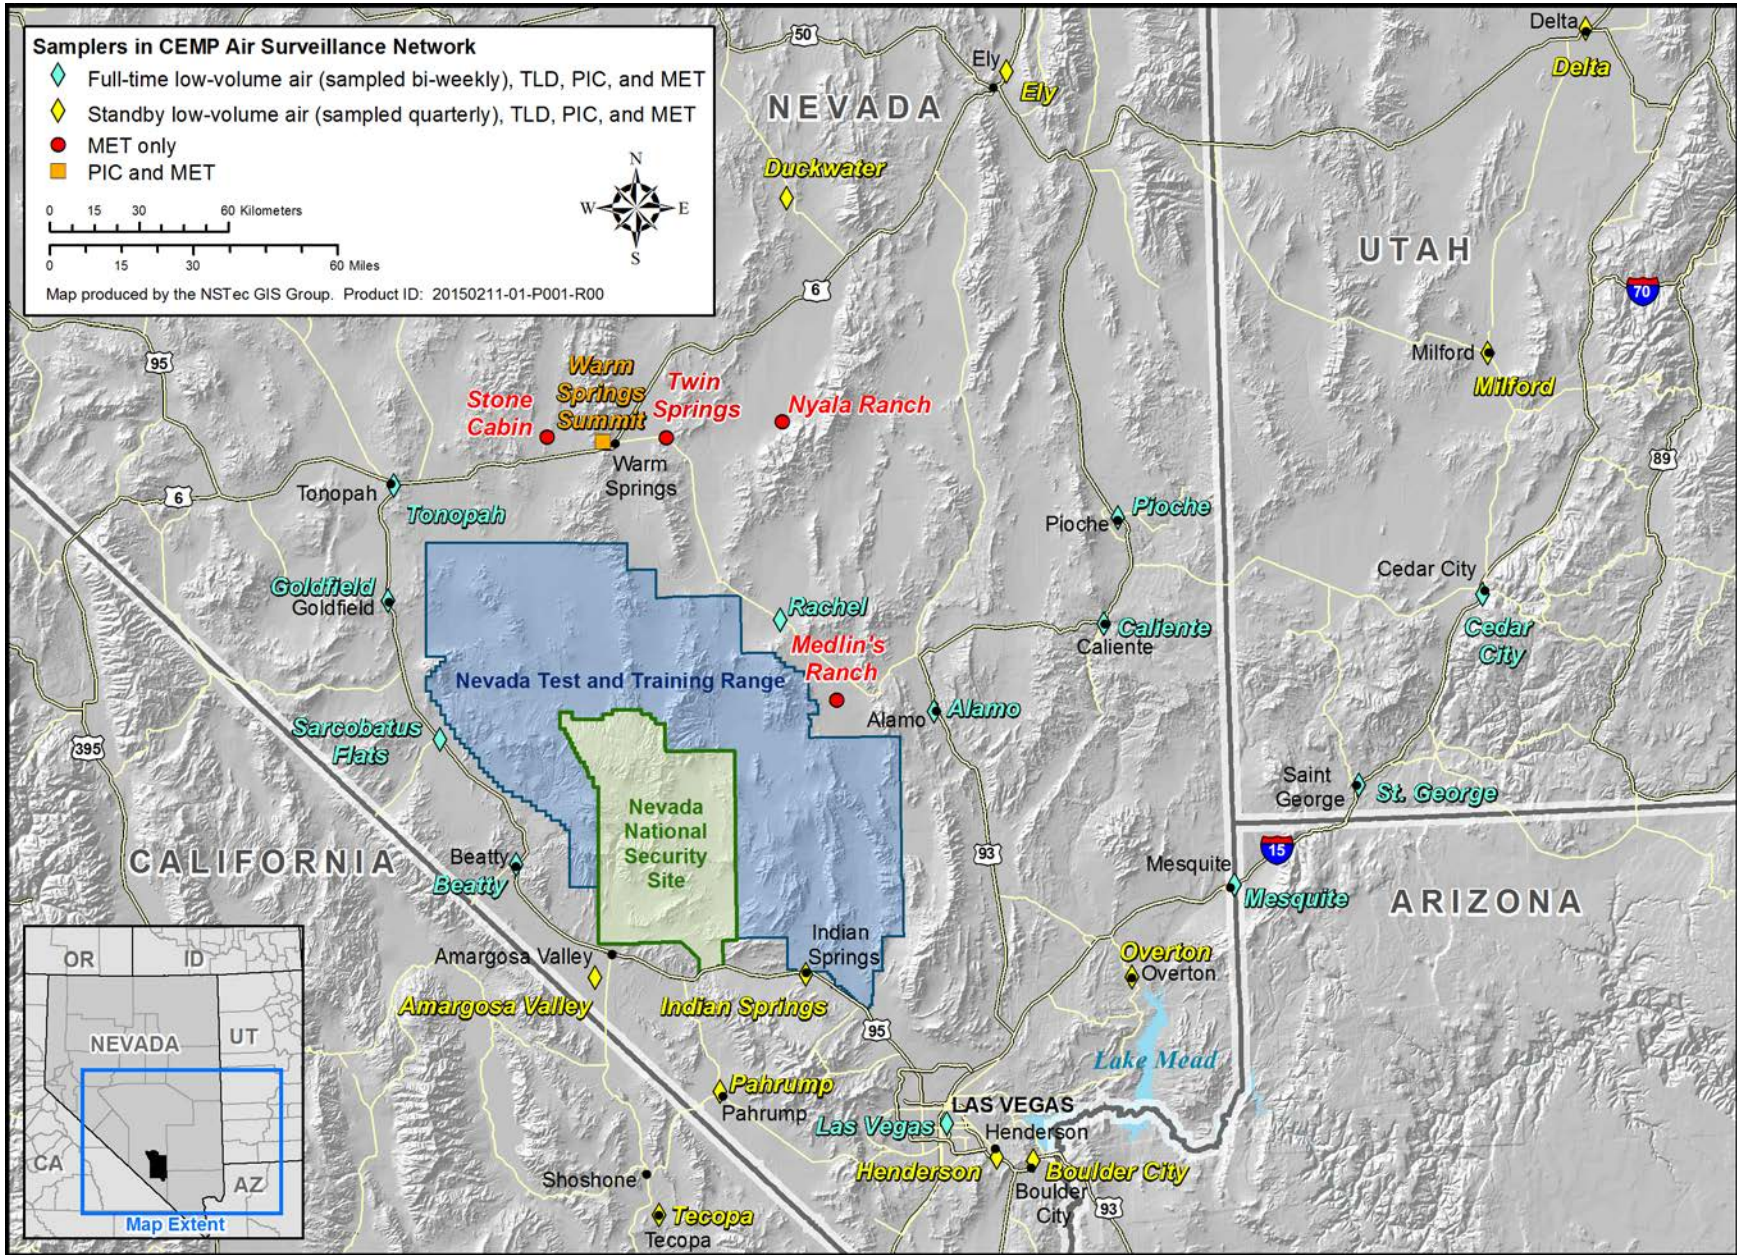

Figure 7-1. 2014 CEMP Air Surveillance Network

samples once each quarter (see Figure 7-1). Warm Springs Summit, Nevada, is the only ASN station where a low-volume air sampler is not located. Duplicate continuously operating air samplers are operated at two randomly selected full-time stations for 3 months (one calendar quarter) before being moved to a new location. Glass-fiber filters from the low-volume particulate samplers are collected by the CEMs and mailed to DRI, where they are prepared and forwarded to an independent laboratory to be analyzed for gross alpha and gross beta activity. Samples are held for a minimum of 7 days after collection to allow for the decay of naturally occurring radon progeny. Upon completion of the gross alpha/beta analyses, the filters are returned to DRI to be composited on a quarterly basis for gamma spectroscopy analysis.

CEMP Thermoluminescent Dosimetry Network – Thermoluminescent dosimetry is used to measure both individual and population external exposure to ambient radiation from natural and artificial sources. In 2014, this network consisted of fixed environmental TLDs at 23 of the 24 CEMP stations (see Figure 7-1). A TLD is not currently deployed at Warm Springs Summit due to limited access during the winter months. The TLD used is a Panasonic UD-814AS. Within the TLD, a slightly shielded lithium borate element is used to check low-energy radiation levels and three calcium sulfate elements are used to measure penetrating gamma radiation. For quality assurance (QA) purposes, duplicate TLDs are deployed at three randomly selected stations. An average daily exposure rate was calculated for each quarterly exposure period. The average of the quarterly values was multiplied by 365.25 days to obtain the total annual exposure for each station.

CEMP Pressurized Ion Chamber (PIC) Network – The PIC detector measures gamma radiation exposure rates and, because of its sensitivity, may detect low-level exposures that go undetected by other monitoring methods. PICs are in place at all 24 stations in the CEMP ASN (see Figure 7-1). The primary function of the PIC network is to detect changes in ambient gamma radiation due to human activities. In the absence of such activities, ambient gamma radiation rates vary naturally among locations, reflecting differences in altitude (cosmic radiation), radioactivity in the soil (terrestrial radiation), and slight variations at a single location due to weather patterns. Because a full suite of meteorological data is recorded at each CEMP station, variations in PIC readings caused by weather events such as precipitation or changes in barometric pressure are more readily identified. Variations can be easily viewed by selecting a station location on the Graph link from the CEMP home page, <http://www.cemp.dri.edu/>, then selecting the desired variables.

CEMP Meteorological (MET) Network – Changing weather conditions can have an effect on measurable levels of background radiation; therefore, meteorological instrumentation is in place at each of the 24 CEMP stations and at the four ranch MET stations that do not monitor airborne radiation: Stone Cabin, Twin Springs, Nyala Ranch, and Medlin's Ranch (see Figure 7-1). The MET network includes sensors that measure air temperature, humidity, wind speed and direction, solar radiation, barometric pressure, precipitation, and soil temperature and moisture data. All of these data can be observed real-time at the onsite station display, and archived data are available by accessing the CEMP home page at <http://www.cemp.dri.edu/>.

Figure 7-2. CEMP Station in Betty, Nevada

7.1.2 Air Sampling Methods

Samples of airborne particulates from CEMP ASN stations were collected by drawing air through a 5-centimeter (2-inch) diameter glass-fiber filter at a constant flow rate of 49.5 liters (1.75 cubic feet [ft³]) per minute at standard temperature and pressure. The actual flow rate and total volume were measured with an in-line air-flow calibrator. The filter is mounted in a holder that faces downward at a height of approximately 1.5 meters (m) (5 feet [ft]) above the ground. The total volume of air collected ranged from approximately 1,030 to 1,290 cubic meters (m³) (36,000 to 45,000 ft³), depending on the elevation of the station and changes in air temperature and/or pressure.

During 2014, CEMP air samples were collected on a bi-weekly basis from the 12 full-time stations. This sampling frequency results in the possible collection of 26 samples per year from each full-time station. At the 11 standby stations, air samples were collected on a quarterly basis (one 2-week sample per quarter), resulting in the collection of only four samples per year.

7.1.3 Air Sampling Results

7.1.3.1 Gross Alpha and Gross Beta

Analyses of gross alpha and beta in airborne particulate samples are used to screen for long-lived radionuclides in the air. The mean annual gross alpha activity across all sample locations was $1.12 \pm 0.28 \times 10^{-15}$ microcuries per milliliter ($\mu\text{Ci}/\text{mL}$) ($4.14 \pm 1.04 \times 10^{-5}$ becquerels [Bq/m^3]) (Table 7-1). Gross alpha was detectable in all of the 2014 air samples, and overall, gross alpha levels of activity were similar to results from previous years. Figure 7-3 shows the long-term maximum, mean, and minimum alpha trend for all CEMP stations combined. The mean gross alpha results show a generally decreasing trend for the past 10 years from 2004 to 2014. This trend is also reflected by most of the stations on an individual basis.

Table 7-1. Gross alpha results for the CEMP offsite ASN in 2014

Sampling Location	Number of Samples	Concentration ($\times 10^{-15} \mu\text{Ci}/\text{mL}$ [$3.7 \times 10^{-5} \text{Bq}/\text{m}^3$])

Mean Minimum Detectable Concentration (MDC; see Glossary, Appendix B) = $0.30 \times 10^{-15} \mu\text{Ci}/\text{mL}$					
Standard Error of Mean MDC = $0.04 \times 10^{-15} \mu\text{Ci}/\text{mL}$					

Figure 7-3. Historical trend for gross alpha analysis for all CEMP stations

The mean annual gross beta activity across all sample locations (Table 7-2) was $1.95 \pm 0.22 \times 10^{-14}$ $\mu\text{Ci/mL}$ ($7.22 \pm 0.081 \times 10^{-4}$ Bq/m^3). Gross beta activity was detected in all air samples and, overall, was similar to previous years' levels. Figure 7-4 shows the long-term maximum, mean, and minimum beta trend for all stations combined. The 2011 spike in the maximum data, observed across all stations in the network, was due to the tsunami-damaged Fukushima Nuclear Power Plant accident in Japan. Except for 2011, mean gross beta results have been essentially level from 2004 to 2014. This trend is also reflected by most of the stations on an individual basis.

Figure 7-4. Historical trend for gross beta analysis for all CEMP stations

7.1.3.2 Gamma Spectroscopy

Gamma spectroscopy analysis was performed on all samples from the low-volume air sampling network. Generally, the filters were composited by station on a quarterly basis after gross alpha/beta analysis. As in previous years, man-made gamma-emitting radionuclides were not detected in any samples. In most of the samples, naturally occurring beryllium-7 (⁷Be) was detectable. This radionuclide is produced by cosmic ray interaction with nitrogen in the atmosphere. The mean annual activity for ⁷Be for the sampling network was $0.48 \pm 0.18 \times 10^{-13}$ μCi/mL

7.1.4 TLD Results

TLDs measure ionizing radiation from all sources, including natural radioactivity from cosmic or terrestrial sources and from man-made radioactive sources. The TLDs are mounted in a plexiglass holder approximately 1 m (3.3 ft) above the ground and are exchanged quarterly. TLD results are not presented for the Warm Springs Summit station at this time because its access is limited in the winter months. This does not allow for a proper quarterly change of the TLD as required. The total annual exposure for 2014 ranged from 72 milliroentgens (mR) (0.72 millisieverts [mSv]) at St. George, Utah, to 158 mR (1.58 mSv) at Sarcobatus Flat, Nevada, with a mean annual exposure of 117 mR (1.17 mSv) for all operating locations. Results are summarized in Table 7-3 and are consistent with previous years' data. Figure 7-5 shows the long-term data trend for the CEMP stations as a whole. Overall, the TLD data show a generally decreasing trend for the past 10 years from 2004 to 2014, although the 2014 results are slightly higher than 2013.

Figure 7-5. Historical trend for TLD analysis for all CEMP stations

7.1.5 PIC Results

The PIC data presented in this section are based on daily averages of gamma exposure rates from each station, with one exception due to equipment failure (see footnote, Table 7-4). Table 7-4 contains the maximum, minimum, and standard deviation of daily averages (in microrentgens per hour [$\mu\text{R}/\text{hr}$]) for the periods during 2014 when telemetry data were available. It also shows the average gamma exposure rate for each station during the year (in $\mu\text{R}/\text{hr}$) as well as the total annual exposure (in milliroentgens per year [mR/yr]). The exposure rate ranged from 70.52 mR/yr (0.71 mSv/yr) in Pahrump, Nevada, to 170.38 mR/yr (1.70 mSv/yr) at Warm Springs, Nevada. Background levels of environmental gamma exposure rates in the United States (from combined effects of terrestrial and cosmic sources) vary between 49 and 247 mR/yr (BEIR III 1980). Averages for selected regions of the United States were compiled by the U.S. Environmental Protection Agency and are shown in Table 7-5. The annual

exposure levels observed at the CEMP stations in 2014 are well within these United States background levels, and are consistent with previous years' exposure rates.

7.1.6 Environmental Impact

Results of analyses conducted on data obtained from the CEMP network of low-volume particulate air samplers, TLDs, and PICs showed no measurable evidence at CEMP station locations of offsite impacts from radionuclides from NNSA/NFO activities. Activity observed in gross alpha and beta analyses of low-volume air sampler filters was consistent with previous years' results and is within the range of activity found in other communities of the United States that are not adjacent to man-made radiation sources. Likewise, no man-made gamma-emitting radionuclides were detected. TLD and PIC results remained consistent with previous years' background levels and are well within average background levels observed in other parts of the United States (see Table 7-5).

Occasional elevated gamma readings (10%–50% above normal average background) detected by the PICs in 2014 were always associated with precipitation events and/or low barometric pressure. Low barometric pressure can result in the release of naturally occurring radon and its daughter products from the surrounding soil and rock substrates. Precipitation events can result in the “rainout” of globally distributed radionuclides occurring as airborne particulates in the upper atmosphere. Figure 7-6, generated from the CEMP website, illustrates an example of this phenomenon.

Figure 7-6. The effect of meteorological phenomena on background gamma readings

7.2 Offsite Surface and Groundwater Monitoring

The CEMP water monitoring program is a non-regulatory public informational and outreach program. It provides the public with water data regarding the presence of man-made radionuclides that could be the result of past nuclear testing on the NNSS. The CEMP, prior to 2014, monitored offsite groundwater wells, surface waters, and springs used for water supplies in areas surrounding the NNSS. Beginning in 2014, the CEMP limited monitoring to groundwater wells in CEMP communities located within the regional groundwater flow system that are downgradient or perceived to be downgradient of the NNSS (Figure 7-7). This was done to increase efficiency and relevancy of the program. Water samples are collected by DRI personnel and analyzed for tritium. Tritium is one of the most abundant radionuclides generated by an underground nuclear test, and because it is a constituent of the water molecule itself, it is also one of the most mobile. DRI provides public access to water monitoring data through CEMP’s website at <http://www.cemp.dri.edu/>.

7.2.1 Sample Locations and Methods

During August 2014, DRI sampled four wells (Table 7-6). Sample locations were selected based upon input from the CEMs participating in the CEMP project in communities located downgradient of the NNSS. All wells were sampled using downhole submersible pumps. Each well was pumped a minimum of 5 to 15 minutes prior to sampling to purge water from the pump tubing and well annulus. This process ensured that the resultant sample was representative of local groundwater. Table 7-6 lists all of the sample points, their locations, the date they were sampled, and the sampling method. The locations of the sample points are shown in Figure 7-7.

Table 7-6. CEMP water monitoring locations sampled in 2014

Monitoring Location Description	Latitude	Longitude	Date Sampled	Sample Collection Method
Amargosa Valley school well	36°34.16"	-116°27.66"	8/26/2014	By hand from sink in office of elementary school
Beatty Water and Sewer municipal water distribution system	36°54.93"	-116°45.66"	8/27/2014	By hand at wellhead at Well #1
Sarcobatus Flat well	37°16.76"	-117°01.10"	8/27/2014	By hand at wellhead
Tecopa residential well	35°50.86"	-116°13.63"	8/05/2014	By hand at residential source

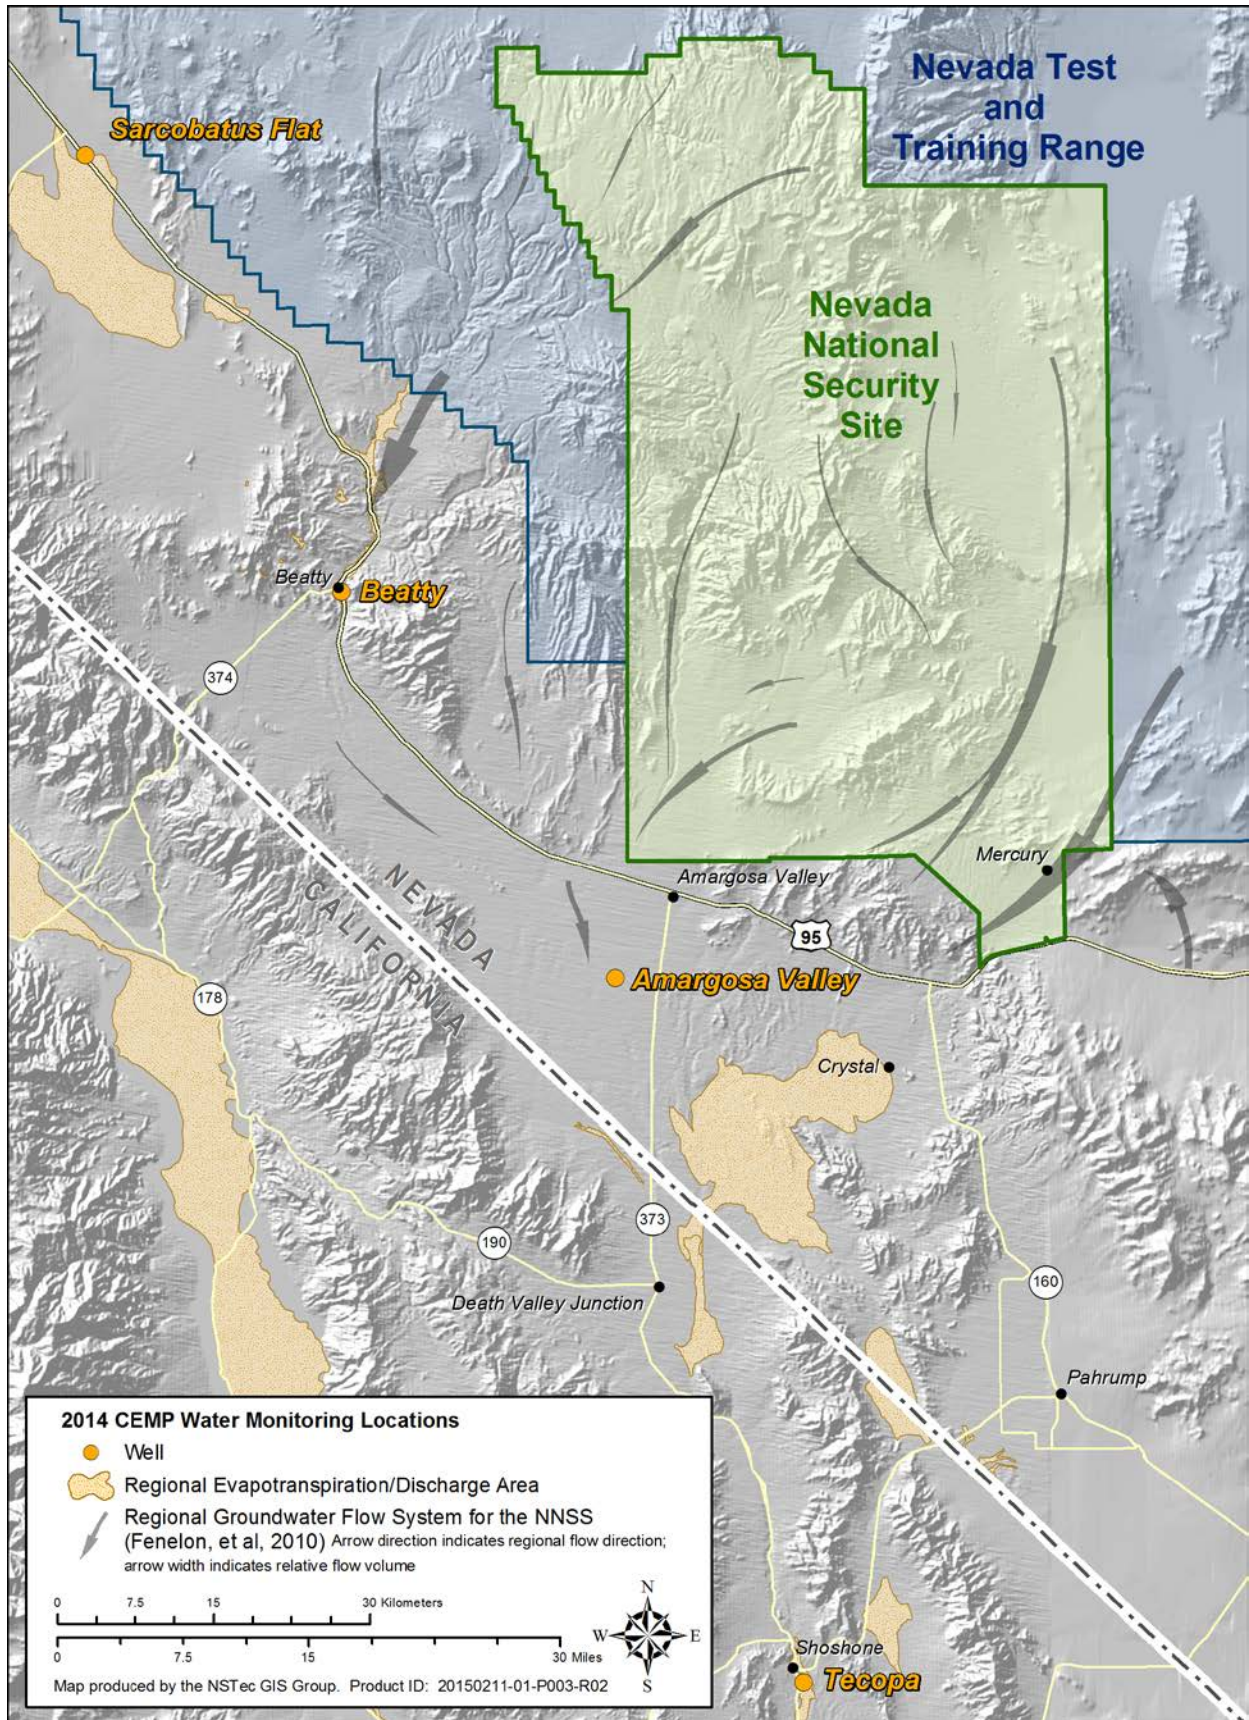

Figure 7-7. 2014 CEMP water monitoring locations

Samples collected in 2014 were analyzed using unenriched scintillation counting at ARS International laboratory in Port Allen, Louisiana. Samples taken prior to 2014 were analyzed using enriched or unenriched gas proportional counting or enriched liquid scintillation counting. Unenriched scintillation counting is an EPA approved method for tritium analysis. The decision level (L_C) (see Glossary, Appendix B) for this counting process was less than 186 picocuries per liter (pCi/L). The L_C is established solely based on the variability of multiple measures of samples used to establish laboratory background. If a sample exceeds this threshold, then it is considered to be distinguishable from background. The MDC (see Glossary, Appendix B) for tritium was approximately 377 pCi/L and is a more rigorous threshold that dictates that the sample be distinguishable from background at a confidence of 95%. The MDC considers both the variability associated with multiple measures of the background as well as the variability associated with multiple measures of the sample itself. The L_C and the MDC are less than 1% and 2% of the EPA limit for tritium in drinking water of 20,000 pCi/L, respectively. Chapter 17 discusses the quality assurance and control procedures used for sampling groundwater.

7.2.2 Results of Groundwater Monitoring

Tritium analyses from ARS International for the four groundwater samples yielded results that were all quantifiably below background (\leq the MDC of approximately 377 pCi/L). Public access to the monitoring data is available on the DRI CEMP website at <http://www.cemp.dri.edu/>.

7.2.3 Environmental Impact

As in previous years, the wells and water supply systems within the CEMP monitoring network downgradient of the NNSS showed no evidence of tritium contamination from past underground nuclear testing on the NNSS. However, in 2009, tritium was detected off site above the tritium standard analysis method MDC in the Underground Test Area characterization well, ER-EC-11, which is approximately 700 m (2,297 ft) west of the NNSS on the Nevada Test and Training Range (NTTR) (see Chapter 11, Section 11.1.1.2 and Figure 11-4). Three wells further off site from the NNSS on NTTR have been found to contain tritium at very low levels using enriched tritium analyses: well ER-EC-6 (5.2 pCi/L), ER-EC-12 (4.2 pCi/L), and PM-3 (237 pCi/L) (see Chapter 5, Table 5-4 and Sections 5.1.3.1 and 5.1.3.3). PM-3 is the farthest well from the NNSS border (approximately 3,000 or 1.8 mi). Additional sampling and analyses are needed to confirm these amounts of tritium. Groundwater characterization and modeling activities are ongoing and will be used to forecast the extent of off site contamination over the next 1,000 years. The nearest CEMP water monitoring locations that are downgradient of the NNSS nuclear testing areas are Amargosa Valley and Beatty, approximately 67 km (42 mi) and 38 km (24 mi), respectively, southwest of Well ER-EC-11.

Chapter 8: Radiological Biota Monitoring

Ronald W. Warren

National Security Technologies, LLC

Historical atmospheric nuclear weapons testing, outfalls from underground nuclear tests, and radioactive waste disposal sites provide sources of potential radiation contamination and exposure to Nevada National Security Site (NNSS) plants and animals (biota). U.S. Department of Energy (DOE) Order DOE O 458.1, “Radiation Protection of the Public and the Environment,” requires that DOE sites monitor radioactivity in the environment to ensure that the public does not receive a radiological dose greater than 100 millirems per year (mrem/yr) from all pathways of exposure, including the ingestion of contaminated plants and animals. DOE O 458.1 also requires monitoring to ensure aquatic and terrestrial plant and animal populations are protected from excessive radiological dose.

Current NNSS land use practices discourage the harvest of plants or plant parts (e.g., pine nuts and wolfberries) for direct consumption by humans. Some edible plant material might be taken off site and consumed, but this is generally not allowed and, if it does occur, is very limited. Game animals on the NNSS might travel off the site and become available through hunting for consumption by the public, which makes the ingestion of game animals the primary potential biotic pathway for potential dose to the public.

Plants and game animals are monitored under the *Routine Radiological Environmental Monitoring Plan (RREMP)* (Bechtel Nevada [BN] 2003). They are sampled annually from contaminated NNSS sites to estimate doses to persons hypothetically consuming them, to measure the potential for radionuclide transfer through the food chain, and to determine if NNSS biota are exposed to radiation levels harmful to their own populations. Biota and soil samples from the Radioactive Waste Management Sites (RWMSs) are also periodically collected to assess the integrity of waste disposal cells. This chapter describes the biota monitoring program designed to meet public and environmental radiation protection regulations (see Section 2.4) and presents the field sampling and analysis results from 2014. The estimated dose to humans potentially consuming NNSS plants and animals and the dose to biota from these radionuclides are presented in Chapter 9.

Radiological Biota Monitoring Goals

Collect and analyze biota samples for radionuclides to estimate the potential dose to humans who may consume plants or game animals from the NNSS (see Chapter 9 for the estimates of dose to humans).

Collect and analyze biota samples for radionuclides to estimate the absorbed radiation dose to NNSS biota (see Chapter 9 for the estimates of dose to NNSS plants and animals).

Collect and analyze soil samples at the Area 3 and Area 5 RWMSs to provide evidence that the burrowing activities of fossorial animals have or have not compromised the integrity of the soil covered waste disposal units.

8.1 Species Selection

The goal for vegetation monitoring is to sample the plants most likely to have the highest contamination within the NNSS environment. They are generally found inside demarcated radiological areas near the “ground zero” locations of historical aboveground or near-surface nuclear tests. The species selected for sampling represent the most dominant life forms (e.g., trees, shrubs, herbs, or grasses) at these sites. Woody vegetation (i.e., shrubs versus forbs or grasses) is sampled because it is reported to have deeper penetrating roots and higher concentrations of tritium (^3H) (Hunter and Kinnison 1998). Woody vegetation also is a major source of browse for game animals that might potentially migrate off site. Grasses and forbs are sampled when present because they are also a source of food for wildlife. Plant parts collected for analysis represent new growth over the past year. Pine nuts from singleleaf pinyon pine trees, which may be consumed by humans, are also sampled periodically.

When determining the potential dose to animals, the goal of sampling is to select species that are most exposed and most sensitive to the effects of radiation. In general, mammals and birds are more sensitive to radiation than fish, amphibians, or invertebrates (DOE Standard DOE-STD-1153-2002, “A Graded Approach for Evaluating

Radiation Doses to Aquatic and Terrestrial Biota”). Because of this, and because no native fish or amphibians are found on the NNSS, the species in Table 8-1 are used to assess potential dose to animals.

The game animals monitored to assess the potential dose to the public meet three criteria: (1) they are a species consumed by humans; (2) they have a home range that overlaps a contaminated site and, as a result, have the potential for relatively high radionuclide body burdens from exposure to contaminated soil, air, water, or plants at the contaminated site; and (3) they are sufficiently abundant at a site that an adequate tissue sample can be acquired for laboratory analysis. These criteria limit the candidate game animals to those listed in Table 8-1. Mule deer, pronghorn antelope, bighorn sheep, and predatory game animals such as mountain lions are only collected as the opportunity arises, that is, if they are found dead on the NNSS (e.g., killed by a predator or accidentally hit by a vehicle). Tissues from species analogous to big game, such as feral horses, may be collected opportunistically as well. If game animals are not sufficiently abundant at a particular site or at a particular time, non-game small mammals may be used as an analog (Table 8-1).

A mountain lion radio-telemetry study is being conducted on the NNSS (see Chapter 15, Table 15-2). Tissue samples from the carcasses of game animals killed by the radio-tracked mountain lions are analyzed for radionuclides whenever possible, and blood collected from captured mountain lions before they are released with radio-collars is analyzed for ³H. Mountain lion fecal samples (scat) are collected near sites where they had made a kill, if available. The scat are analyzed for ³H to determine if the mountain lion had been exposed to ³H. Soil near the scat is also sampled and analyzed for ³H to determine if it could have contaminated the fecal sample.

The sampling strategy used to assess the integrity of radioactive waste containment includes sampling plants, animals, and soil excavated by ants or small mammals on top of waste covers. Plants are generally selected by size with preference for larger shrubs, under the assumption that they have deeper roots and therefore would be more likely to penetrate buried waste. Small mammals selected for sampling meet three criteria: (1) they are fossorial (i.e., they burrow and live predominantly underground), (2) they have a home range small enough to ensure that they reside a majority of the time on the waste disposal site, and (3) they are sufficiently abundant at a site to acquire an adequate tissue sample for laboratory analysis. These criteria limit the animals to those listed in Table 8-1. Soils excavated by ants or small mammals are also selected for sampling on the basis of size, with preference for larger ant mounds and animal burrow sites under the assumption that these burrows are deeper and have a higher potential for penetrating waste.

Table 8-1. NNSS animals monitored for radionuclides

Small Mammals	Large Mammals	Birds
Game Animals Monitored for Dose Assessments		
Cottontail rabbit (<i>Sylvilagus audubonii</i>)	Mule deer (<i>Odocoileus hemionus</i>)	Mourning dove (<i>Zenaida macroura</i>)
Jackrabbit (<i>Lepus californicus</i>)	Pronghorn antelope (<i>Antilocapra americana</i>)	Chukar (<i>Alectoris chukar</i>)
	Mountain lion (<i>Puma concolor</i>)	Gambel’s quail (<i>Callipepla gambelii</i>)
	Bighorn sheep (<i>Ovis canadensis nelsoni</i>)	
	Bobcat (<i>Lynx rufus</i>)	
Animals Monitored for Integrity of Radioactive Waste Containment or as Game Animal Analogs		
Kangaroo rats (<i>Dipodomys</i> spp.)		
Mice (<i>Peromyscus</i> spp.)		
Antelope ground squirrel (<i>Ammospermophilus leucurus</i>)		
Desert woodrat (<i>Neotoma lepida</i>)		

8.2 Site Selection

The monitoring program design focuses on sampling sites that have the highest concentrations of radionuclides in other media (e.g., soil and surface water) and have relatively high densities of candidate animals. The RREMP identifies five contaminated sites and their associated control sites. Each year, biota from one or two of these sites is sampled, and each of the sites is sampled once every 5 years. They are E Tunnel Ponds, Palanquin/ Schooner Crater, Sedan Crater, T2, and Plutonium Valley (Figure 8-1), and each is associated with one type of a legacy contamination area (see list below). The control site selected for each contaminated site has similar biological and physical features. Control sites are sampled to document the radionuclide levels representative of background.

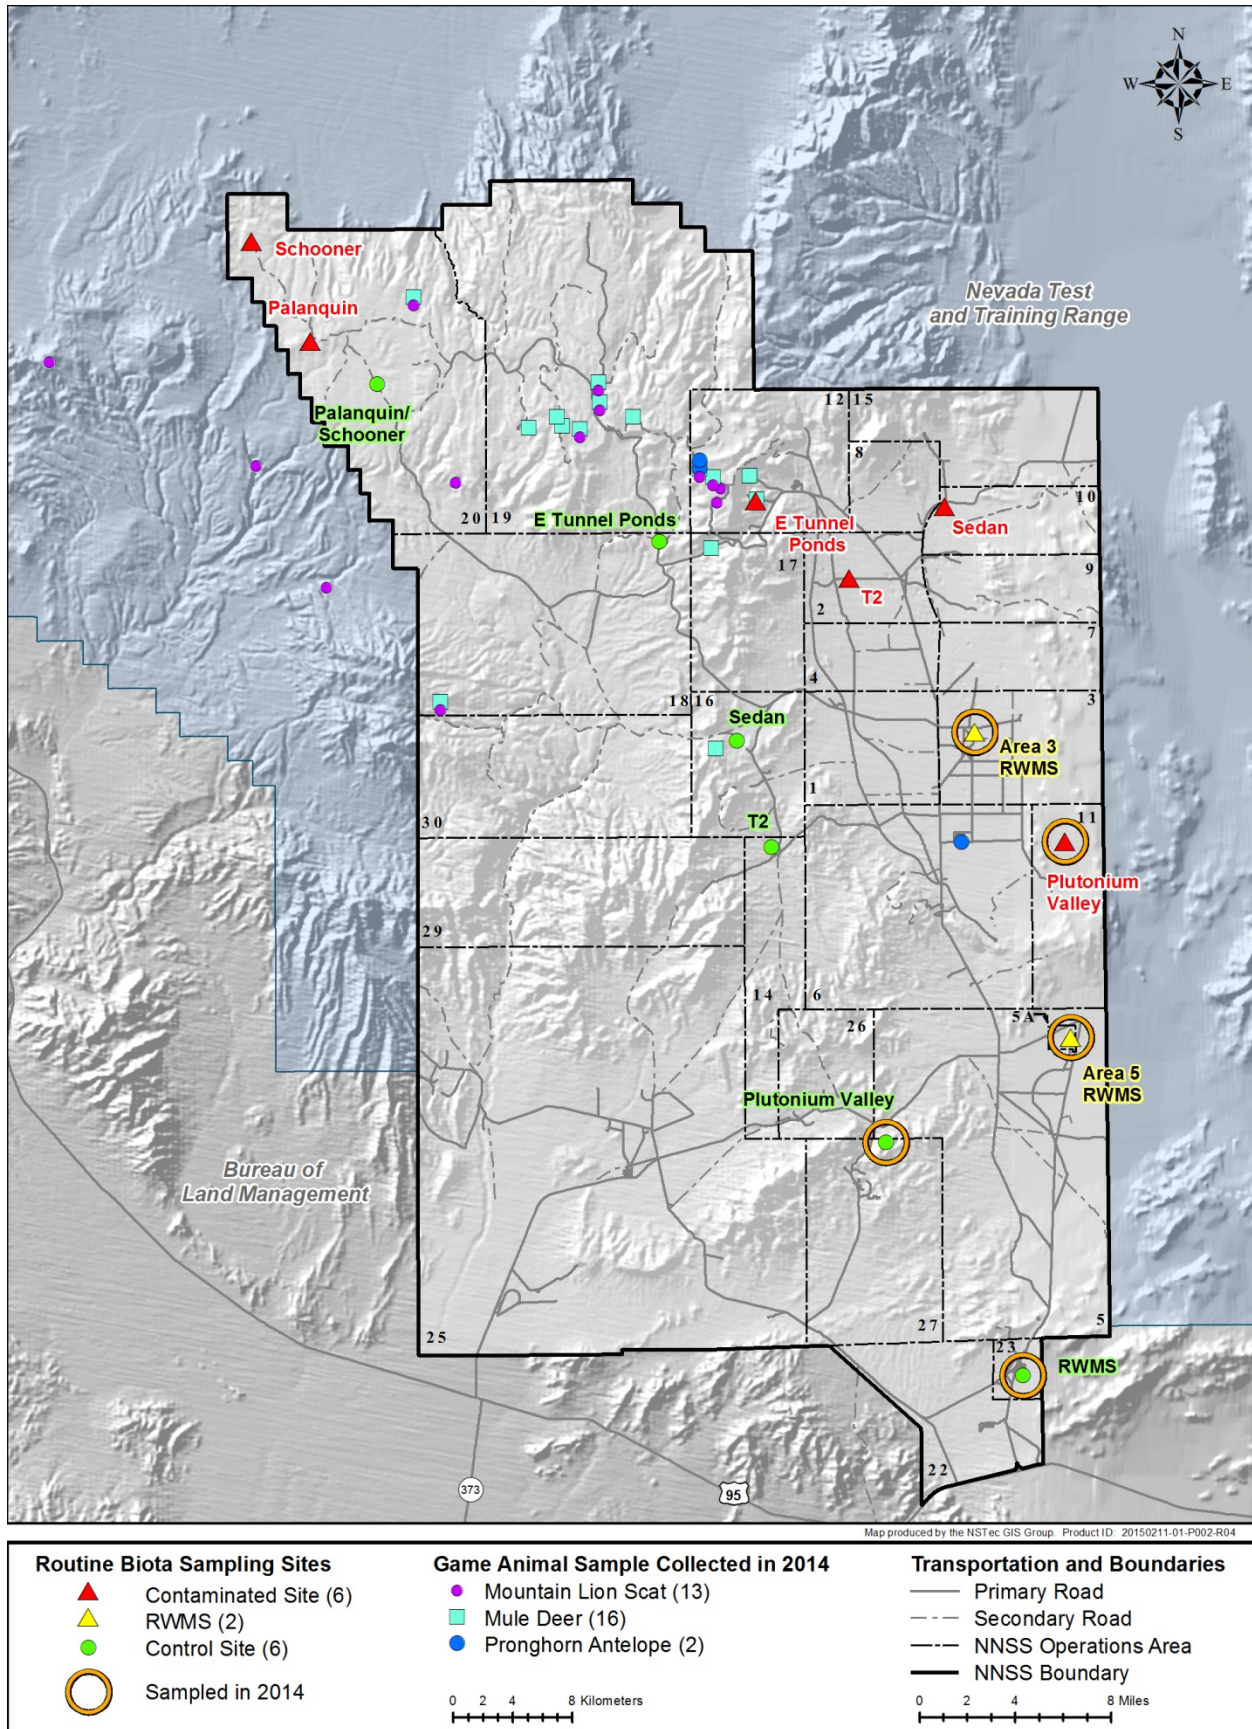

Figure 8-1. Radiological biota monitoring sites on the NNSS

- **Runoff areas or containment ponds associated with underground or tunnel test areas.** Contaminated water draining from test areas can form surface water sources that are important given the limited availability of surface water on the NNSS. Therefore, they have a high potential for transferring radionuclides to plants and wildlife seeking surface water. The associated monitoring site is E Tunnel Ponds below Rainier Mesa. It was last sampled in 2012.
- **Plowshare sites in alluvial fill at lower elevations with high surface contamination.** The historical Plowshare program, conducted throughout the NNSS, explored the potential use of nuclear weapons for peaceful purposes. Subsurface nuclear detonations at these alluvial, low elevation sites have distributed contaminants over a wide area, usually in the lowest precipitation areas of the NNSS. The associated monitoring site is Sedan Crater in Yucca Flat. It was last sampled in 2010.
- **Plowshare sites in bedrock or rocky fill at higher elevations with high surface contamination.** Subsurface nuclear detonations at these Plowshare program sites distributed contaminants over a wide area, usually in the highest precipitation areas of the NNSS. Two monitored sites are in this category: Palanquin Crater and Schooner Crater. Both sites were last sampled in 2013.
- **Atmospheric test areas.** These sites have highly disturbed soils due to the removal of topsoil during historical cleanup efforts and due to the sterilization of soils from heat and radiation during testing. The same areas were often used for multiple nuclear tests. The associated monitoring site is T2 in Yucca Flat. It was last sampled in 2011.
- **Aboveground safety experiment sites.** These areas are typified by current radioactive soil contamination, primarily in the form of plutonium and uranium. The associated monitoring site is Plutonium Valley in Area 11. This contaminated site, along with its control site, was sampled for biota in 2014.

Soil sampling is also conducted periodically at radioactive waste disposal locations on the NNSS to assess whether fossorial small mammals are being exposed to buried wastes and, therefore, whether the integrity of waste containment is compromised. Two radioactive waste disposal facilities are sampled:

- **Area 3 RWMS.** Waste disposal cells within the Area 3 RWMS are subsidence craters resulting from underground nuclear testing. Two closed cells containing bulk low-level radioactive waste are craters U-3ax and U-3bl, which were combined to form the U-3ax/bl disposal unit (Corrective Action Unit 110). U-3ax/bl is covered with a vegetated, native alluvium closure cover that is at least 2.4 meters (m) (8 feet [ft]) thick. It was sampled in 2014.
- **Area 5 RWMS.** Waste disposal has occurred at the Area 5 RWMS since the early 1960s. There are 11 closed disposal cells containing bulk low-level radioactive waste. The cells are unlined pits and trenches that range in depth from 4.6 to 15 m (15 to 48 ft). Efforts are currently being made to establish native vegetation on the cover cap of the 92-Acre Area, which caps multiple waste cells. The cover cap is approximately 2.4 m (8 ft) thick. Plants and animals from three different portions of the 92-Acre Area cover were sampled in 2014.

8.3 2014 Biota Sampling and Analysis

Plutonium Valley, located in Area 11 on the eastern edge of the NNSS at an elevation of 1,250 m (4,100 ft), was sampled in 2014 (Figure 8-1). Four safety experiments were conducted in Plutonium Valley from November 1, 1955, through January 18, 1956, in which conventional explosives were used on nuclear weapons. In one of these tests, there was a slight yield that resulted in the production of fission products (e.g., ^{137}Cs and ^{90}Sr), but the primary contaminant produced and dispersed in the area was plutonium. A control area for Plutonium Valley is located about 24 kilometers (km) (14.9 miles [mi]) southwest of the sample site (Figure 8-1). Any of the candidate game species could be present in Plutonium Valley or at the control site.

The Area 3 RWMS, Area 5 RWMS, and their single control site in Area 23 (Figure 8-1) were also sampled in 2014. The Area 3 RWMS is in Yucca Flat at an elevation of 1,223 m (4,012 ft). Yucca Flat was one of several primary nuclear test areas. Between 1952 and 1972, 60 nuclear weapons tests were conducted within 400 m (1,312 ft) of the Area 3 RWMS boundary. Fourteen of these tests were atmospheric, which left primarily ^3H , ^{90}Sr , ^{137}Cs , ^{152}Eu , $^{239+240}\text{Pu}$, and ^{241}Am in the surface soil across the area. Sampling in 2014 was conducted on the U-3ax/bl cover. The control location was in Area 23.

The Area 5 RWMS is in northern Frenchman Flat at an elevation of 962 m (3,156 ft) and consists of numerous landfill cells. Buried radioactive materials at the Area 5 RWMS consist primarily of ^3H , ^{90}Sr , ^{137}Cs , uranium (various isotopes), plutonium (various isotopes), and ^{241}Am . No nuclear weapons testing occurred within the boundaries of the Area 5 RWMS, but there were 10 underground tests within 4.3 km (2.7 mi) and 14 atmospheric tests within 7 km (4.3 mi). Sampling was conducted on the 92-acre cover.

8.3.1 Plants

Plant sampling took place at Plutonium Valley on July 3, 2014, and at the control site on July 2, 2014. Three composite samples were collected from each location. Plants were sampled over an area of about 0.034 square kilometers (km^2) (0.013 square miles [mi^2]) inside the Plutonium Valley Contamination Area. Plants were collected over a smaller area (0.008 km^2 [0.003 mi^2]) at the control site. All samples consisted of about 150 to 500 grams (g) (5.3 to 17.6 ounces [oz]) of fresh-weight plant material and were composites of material from 7 to 11 plants of the same species. The species sampled represent the dominant vegetation at each site (Table 8-2).

Plant sampling at the Area 3 and Area 5 RWMS took place August 27, 2014. Three composite samples were taken at each of the RWMSs locations and one composite sample was taken at the single RWMS control location in Area 23. All samples consisted of 150 to 500 g (5.3 to 17.6 oz) of fresh-weight plant material from a single species, except at Area 5 RWMS, where each composite sample included both HAGL and Salsola (Table 8-2). The species sampled represent the dominant vegetation at each site.

Plant leaves and stems were hand-picked and stored in airtight Mylar bags. Rubber gloves were used by samplers and changed between each composite sample. Samples were labeled and stored in an ice chest and delivered to the laboratory within 4 hours after they were collected. Water was separated from the samples by distillation. Water and dried plant tissues were submitted to a commercial laboratory for analysis. Water from plants was analyzed for ^3H . Dried plant tissue was submitted for analysis of americium-241 (^{241}Am), strontium-90 (^{90}Sr), plutonium-238 (^{238}Pu), plutonium-239+240 ($^{239+240}\text{Pu}$), and gamma emitting radionuclides (including cesium-137 [^{137}Cs]).

Table 8-2. Plant samples collected in 2014

Common Name	Scientific Name	Name Code	Plutonium Valley	Plutonium Valley Control	Area 3 RWMS	Area 3 RWMS Control	Area 5 RWMS	Area 5 RWMS Control
Indian ricegrass	<i>Achnatherum hymenoides</i>	ACHY	X					
White bursage	<i>Ambrosia dumosa</i>	AMDU				X		X
Four-wing saltbush	<i>Atriplex canescens</i>	ATCA	X	X	X			
Nevada (Flatcrown) buckwheat	<i>Eriogonum deflexum</i>	ERDI		X				
Halogeton	<i>Halogeton glomeratus</i>	HAGL					X	
Basin wildrye	<i>Leymus cinereus</i>	LECI		X				
Russian thistle (unknown species)	<i>Salsola</i> spp.	Salsola					X	
Prince's Plume	<i>Stanleya pinnata</i>	STPI	X					

Results of radiological analyses of plant samples are listed in Table 8-3. As expected, more man-made radionuclides were detected, and in higher concentrations, in samples from the monitored sites (Plutonium Valley, Area 3 RWMS, and Area 5 RWMS) compared with their control sites. Radionuclides detected in the most samples were ^3H (100% of all samples from Area 3 RWMS and Area 5 RWMS), $^{239+240}\text{Pu}$ (100% of samples from Plutonium Valley, Area 3 RWMS, and Area 5 RWMS), ^{238}Pu (100, 33.3, and 66.7% of samples from Plutonium Valley, Area 3 RWMS, and Area RWMS, respectively), and ^{241}Am (100% of samples from Plutonium Valley and 33.3% of samples from Area 3 RWMS). Concentrations of $^{239+240}\text{Pu}$ and, to a lesser extent ^{241}Am , in plants sampled from Plutonium Valley were higher in 2014 samples compared with samples collected in 2004 and 2009 (Figure 8-3). This is likely due to the fact that 2014 samples were collected much closer to the ground zero locations in Plutonium Valley. Concentrations of ^3H in water observed in plants sampled from the Area 3 and the Area 5 RWMS during 2014 were within the range of values observed since 1999 (Figure 8-4).

Table 8-3. Concentrations of man-made radionuclides in plants sampled in 2014

Sample	Radionuclide Concentrations ± Uncertainty ^(a)				
	³ H (pCi/L) ^(b)	⁹⁰ Sr (pCi/g) ^(c)	²³⁸ Pu (pCi/g) ^(c)	²³⁹⁺²⁴⁰ Pu (pCi/g) ^(c)	²⁴¹ Am (pCi/g) ^(c)

8.3.2 Animals

State and federal permits were secured to trap specific small mammals and birds in 2014 and to opportunistically sample large mammal mortalities (e.g., from vehicles or from predation) on the NNSS. Animal trapping took place at the Plutonium Valley and Plutonium Valley Control locations from July 21 through September 29, 2014, and at the Area 3 and Area 5 RWMS locations August 27 and 28, 2014. All animal samples are described in Table 8-4. Two pronghorn antelope killed by vehicles, a fawn mule deer found in the road, and a male mule deer killed by an unknown mountain lion (all on the NNSS) were also sampled during 2014 (Table 8-4). Though muscle is usually the only portion consumed by humans, the rabbits were homogenized to give a more conservative (higher) estimate of potential dose to someone consuming them (see Section 9.1.1.2). The whole bodies of the small mammals sampled from the RWMSs were also homogenized to determine full body burden of radionuclides in order to assess whether they were in contact with the waste. Water was distilled from the homogenized samples and submitted to a laboratory for ^3H analysis, and the remaining tissue samples were submitted for ^{90}Sr , ^{238}Pu , $^{239+240}\text{Pu}$, ^{241}Am , and gamma spectroscopy analysis.

In addition, game animal and mountain lion samples were collected in conjunction with an ongoing mountain lion study (see Chapter 15, Table 15-2) to supplement the analysis of mountain lion habitat use and diet with information on their exposure to radionuclides. Only one collared male mountain lion (NNSS7) remained in the study during 2014. Numerous sites where NNSS7 had made a kill (called kill sites) were visited, and tissue samples from the remains of his prey were sampled whenever possible; these consisted of 14 mule deer samples (Table 8-4). Such tissue samples were generally quite small; therefore, the only analysis conducted on most of them was ^3H in water distilled from the sample; these samples are listed as "water" samples in Table 8-4 under the Sample Description column. In two instances, there was enough muscle tissue available for analysis of ^3H , ^{90}Sr , ^{238}Pu , $^{239+240}\text{Pu}$, ^{241}Am , and gamma-emitting radionuclides. Thirteen fecal samples (scat) from NNSS7 kill sites were collected, including two from the Nevada Test and Training Range (NTTR) (Table 8-4). Each scat sample was paired with a soil sample; the soil was collected near the scat but far enough away to not be contaminated by it. These were taken as background for the scat samples. The scat and soil samples associated with mountain lion NNSS7 were only analyzed for the presence of ^3H .

Man-made radionuclides were detected in all animals collected at Plutonium Valley, Area 3 RWMS, Area 5 RWMS, and all of the opportunistic big-game samples (Table 8-5). Activity levels were dominated by $^{239+240}\text{Pu}$ in Plutonium Valley samples and by ^3H in the RWMS and opportunistic samples. A low concentration of $^{239+240}\text{Pu}$, 80 or more times lower than that measured at Plutonium Valley, was measured in the cottontail rabbit collected from the Plutonium Valley Control location. As expected, concentrations of ^3H were much higher in animals collected from waste covers at the Area 3 and Area 5 RWMSs compared with those at the RWMS Control location. $^{239+240}\text{Pu}$ was also measured in one Area 3 RWMS sample at a much higher concentration than observed at the Area 5 RWMS or the RWMS Control location.

Concentrations of man-made radionuclides in samples collected in conjunction with the mountain lion study are listed in chronological order in Table 8-6. No ^3H was detected in the adjacent soil samples so it is unlikely that ^3H in the scat came from the immediate environment. Tritium was detected in both mule deer and NNSS7 scat samples, which is expected, given the fact that mule deer are known to use certain water sources containing ^3H , especially E Tunnel Pond in Area 12. Of the two NNSS7 prey animals analyzed for other radionuclides, one (NNSS7-128 from Area 19) had concentrations of $^{239+240}\text{Pu}$ and ^{241}Am greater than its minimum detectable concentrations (MDCs). NNSS7 scat samples at four locations contained levels of ^3H above their MDCs.

8.3.3 Soil

Sampling of soil at the Area 3 and Area 5 RWMSs took place on August 27, 2014. Three samples of soil brought to the surface from either small mammal or ant burrowing activity were collected from each of the RWMSs, and soil from one small mammal burrow was sampled from the RWMS Control location in Area 23 (Table 8-7). Each sample consisted of about 500 g (17.6 oz) of dry soil, which was submitted to a commercial laboratory for analysis of ⁹⁰Sr, ²³⁸Pu, ²³⁹⁺²⁴⁰Pu, ²⁴¹Am, uranium, and gamma-emitting radionuclides (which includes ¹³⁷Cs).

Man-made radionuclides were detected in all soil samples (Table 8-8). The soil samples from the Area 3 and Area 5 RWMSs had relatively higher concentrations of ⁹⁰Sr, but lower concentrations of ²³⁸Pu, ²³⁹⁺²⁴⁰Pu, and ²⁴¹Am, compared to the control location, where the levels of these radionuclides in the undisturbed surface soil are attributable to worldwide fallout. If small mammals and/or ants were in contact with the waste at the RWMSs, then it would be expected that concentrations of all radionuclides would be elevated at these locations and that fission products other than ⁹⁰Sr (e.g., ¹³⁷Cs) would also be observed. Because this was not the case, it does not appear that small mammals and ants are in contact with, or are bringing to the surface, buried waste. Uranium was detected in all soil samples but the isotopic ratios and concentrations indicate that it is from natural and not man-made sources.

Table 8-7. Animal excavated soil samples collected in 2014

Location	Sample Name	Sample Description
Area 3 RWMS	Soil #1	Soil from 1 small mammal colony (likely kangaroo rats)
	Soil #2	Soil from 1 small mammal colony (likely kangaroo rats)
	Soil #3	Soil from 1 small mammal colony (likely kangaroo rats)

8.4 Data Assessment

Biota sampling results confirm that man-made radionuclide concentrations are generally higher at monitored locations (Plutonium Valley, Area 3 RWMS, and the Area 5 RWMS) compared with their control locations. Elevated concentrations of ³H in vegetation at both RWMSs indicate that ³H in soil moisture at the root zone is elevated at both sites. This does not necessarily indicate that the roots of these plants have penetrated the waste zone, but more likely indicates that ³H is highly mobile and is moving away from the waste as water moving upward through the soil profile. This is supported by the lack of other radionuclides which would also be highly elevated if the plant's roots had invaded the buried waste. Also, soil samples do not suggest burrowing animals have come into contact with buried waste either. It is likely that elevated ³H concentrations in animals come from their consuming plants on the covers and from inhalation of ³H evaporating from the soil. Though NNS-related radionuclides are detected in some plants and animals, the levels pose negligible risk to humans and biota. The potential dose to a person hunting and consuming these animals is well below dose limits to members of the public (see Section 9.1.1.2). Also, radionuclide concentrations were below levels considered harmful to the health of the plants or animals; the dose resulting from observed concentrations were less than 4 percent of dose limits set to protect populations of plants and animals (see Section 9.2).

Chapter 9: Radiological Dose Assessment

Ronald W. Warren and Mark McMahon

National Security Technologies, LLC

The U.S. Department of Energy (DOE) requires DOE facilities to estimate the radiological dose to the general public and to plants and animals in the environment caused by past or present facility operations. These requirements are specified in DOE Orders DOE O 435.1, “Radioactive Waste Management,” and DOE O 458.1, “Radiation Protection of the Public and the Environment” (see Section 2.4). To estimate these radiological doses, radionuclide concentration data gathered on the Nevada National Security Site (NNSS) are used along with dose conversion factors published in DOE Technical Standard DOE-STD-1196-2011. The dose conversion factors take into account the different population fractions of age and sex to give representative dose coefficients for a reference person within the U.S. population. The 2014 data used are presented in Chapters 4, 5, 6, and 8 of this report and include the results for onsite monitoring of air, water, direct radiation, and biota, and for offsite monitoring of groundwater. The independent offsite air and groundwater data presented in Chapter 7, Community Environmental Monitoring Program (CEMP), provide extra assurance to the public that estimated doses do not underestimate potential offsite exposures to NNSS-related radiation. The specific goals for the dose assessment component of radiological monitoring are shown below.

Radiological Dose Assessment Goals

Determine w the maximum radiation dose to a member of the general public from airborne radionuclide emissions at the NNSS complies with the Clean Air Act, National Emission Standards for Hazardous Air Pollutants (NESHAP) limit of 10 millirems per year (mrem/yr) (0.1 millisieverts per year [mSv/yr]).

Determine if radiation levels from the Radioactive Waste Management Sites (RWMSs) comply with the 25 mrem/yr (0.25 mSv/yr) dose limit to members of the public as specified in DOE Manual DOE M 435.1-1, “Radioactive Waste Management Manual.”

Determine if the total radiation dose (total effective dose equivalent [TEDE], see Glossary, Appendix B) to a member of the general public from all possible pathways (direct exposure, inhalation, ingestion of water and food) as a result of NNSS operations complies with the limit of 100 mrem/yr (1 mSv/yr) established by DOE O 458.1.

Determine if the radiation dose (in a unit of measure called a rad [see Glossary, Appendix B]) to NNSS biota complies with the following limits set by DOE Standard DOE-STD-1153-2002, “A Graded Approach for Evaluating Radiation Doses to Aquatic and Terrestrial Biota”:

- < 1 rad per day (rad/d) for terrestrial plants and aquatic animals
- < 0.1 rad/d for terrestrial animals

9.1 Dose to the Public

This section identifies the possible pathways by which the public could be exposed to radionuclides due to past or current NNSS activities. It describes how field monitoring data are used with other NNSS data sources (e.g., radionuclide inventory data) to provide input to the dose estimates and presents the estimated 2014 public dose attributable to U.S. Department of Energy, National Nuclear Security Administration Nevada Field Office (NNSA/NFO) activities from each pathway and all pathways combined. The public dose due to radioactive waste operations on the NNSS is also assessed, and a description of the program that controls the release of NNSS materials having residual radioactivity into the public domain is provided.

9.1.1 Dose from Possible Exposure Pathways

As prescribed in the *Routine Radiological Environmental Monitoring Plan* (Bechtel Nevada [BN] 2003), air, groundwater, and biota are routinely sampled to document the amount of radioactivity in these media and to provide data that can be used to assess the radiation dose received by the general public from several pathways.

The potential pathways by which a member of the general public residing off site might receive a radiation dose resulting from past or present NNSS operations include the following:

- Inhalation of, ingestion of, or direct external exposure to airborne radionuclide emissions transported off site by wind
- Ingestion of wild game animals that drink from surface waters and/or eat vegetation containing NNSS-related radioactivity
- Ingestion of plants containing radioactivity from NNSS-related activities
- Drinking water from underground aquifers containing radionuclides that have migrated from the sites of past underground nuclear tests or waste management sites
- Exposure to direct radiation along the borders of the NNSS

The subsections below address all of the potential pathways and their contribution to public dose estimated for 2014.

9.1.1.1 Dose from NNSS Air Emissions

Six air particulate and tritium (³H) sampling stations located near the boundaries and the center of the NNSS are approved by the EPA Region IX as critical receptor samplers to demonstrate compliance with the NESHAP public dose limit of 10 mrem/yr (0.1 mSv/yr) from air emissions. The annual average concentration of an airborne radionuclide must be less than its NESHAP Concentration Level for Environmental Compliance (abbreviated as compliance level [CL]) (see Table 4-1 of Section 4.1.1). The CL for each radionuclide represents the annual average concentration of that radionuclide in air that would result in a TEDE of 10 mrem/yr. If multiple radio-nuclides are detected at a station, then compliance with NESHAP is demonstrated when the sum of the fractions (determined by dividing each radionuclide’s concentration by its CL and then adding the fractions together) is less than 1.0.

The critical receptor sampling stations can be thought of as worst case for an offsite receptor because these samplers are much closer to emissions sources. Table 9-1 displays the distances between the critical receptor monitoring stations and points where members of the public potentially live, work, and/or go to school. The distance between the sampling location and the closest onsite emission location (see Chapter 4, Figure 4-1) is also listed.

Table 9-1. Distance between critical receptor air monitoring stations and nearest points of interest

Critical Receptor Station	Distance ^(a) and Direction ^(b) to Nearest Offsite Locations and Onsite Emission Location			
	Residence	Business/Office	School	NNSS Emission Source

Area 25, Gate 510	4 km S Amargosa Valley	3.5 km S Amargosa Valley	15 km SW Amargosa Valley	5.1 km NE Area 25, nearest portion of Grouped Area Sources

(a) Distance is shown in kilometers (km). For miles, multiply by 0.62.
 (b) N=north, S=south, E=east, W=west in all direction combinations shown

In 2014, the man-made radionuclides detected in samples from at least one of the six critical receptor air monitoring stations included ³H, americium-241 (²⁴¹Am), plutonium-238 (²³⁸Pu), and plutonium-239+240 (²³⁹⁺²⁴⁰Pu) (see Section 4.1.4). The annual average concentrations of these radionuclides were well below their CLs, and the sum of fractions for each location were all less than 1.0 (see Section 4.1.5, Table 4-9). As in previous years, the 2014 data from the six critical receptor stations show that the NESHAP public dose limit of 10 mrem/yr (0.1 mSv/yr) was not exceeded.

The shortest distance between where a member of the public resides and a critical receptor monitoring station is 4 km (2.5 miles [mi]): between the Gate 510 sampler in the southwest corner of the NNSS and the northern edge of the community of Amargosa Valley. Because it is the closest, the results from the Gate 510 sampler (see Table 4-9) are believed to be most representative of air concentrations to which the public is continuously exposed. Scaling the 0.002 sum of fractions for the Gate 510 station to the 10 mrem/yr (0.1 mSv/yr) limit gives an estimated dose of 0.02 mrem/yr (0.0002 mSv/yr) from radionuclides in air. More detailed information regarding the estimation of the dose to the public from airborne radioactivity in 2014 from all activities conducted by NNSA/NFO on the NNSS and its Nevada support facilities is reported in National Security Technologies, LLC (NSTec 2015).

9.1.1.2 Dose from Ingestion of Game Animals from the NNSS

Two game species, mule deer and mourning doves, have been shown to travel off the NNSS and be available to hunters (Giles and Cooper 1985; NSTec 2009). Because of this, game animals on the NNSS are sampled annually near known radiologically contaminated areas to give conservative (worst-case) estimates of the level of radionuclides that hunters may consume if these animals are harvested off of the NNSS. In 2014, the following animals were sampled (see Chapter 8, Figure 8-1 and Tables 8-4, 8-5, and 8-6):

- Two jackrabbits from Plutonium Valley (Area 11)
- One cottontail rabbit from the Plutonium Valley Control location (Area 27)
- Two composite samples of small mammals collected from the Area 3 Radioactive Waste Management Site (RWMS)
- Three composite samples of small mammals from the Area 5 RWMS
- One composite small mammal sample from the RWMS Control location (Area 23)
- Two pronghorn antelope (Area 6) accidentally killed by vehicles
- Two mule deer, one found near a road in Area 17 killed by unknown means and one killed by an unknown mountain lion in Area 12
- Fourteen mule deer, each killed by a radio-collared mountain lion (four from Area 12; one each from Areas 16, 18, and 20; and seven from Area 19)
- Thirteen scat samples from one radio-collared mountain lion (four from Area 12, one from Area 18, three from Area 19, two from Area 20, and three from the Nevada Test and Training Range (NTTR))

For the purpose of predicting dose to someone consuming these animals, the composite small mammal samples collected at the RWMS sites are used as analogs for cottontail rabbits and the concentration of tritium in the mountain lion was set equal to that measured in the scat samples.

The potential committed effective dose equivalent (CEDE) (see Glossary, Appendix B) to an individual from consuming game animals was calculated using all animals sampled in 2014 whether or not they had concentrations of man-made radionuclides above the minimum detectable concentration (MDC; see Glossary, Appendix B). If the analytical result for radionuclide concentration in the sample was a negative value (resulting from a background measurement higher than what was observed in the sample), then the dose from consuming that sample was set to zero. The following assumption/parameters were also used to estimate dose:

- An individual consumes all meat from one jackrabbit (513 grams [g]), one cottontail rabbit (167 g), one pronghorn antelope (20.0 kilograms [kg]), one mountain lion (21.3 kg), and one mule deer (35.4 kg) during the year.
- The moisture content of the muscle tissue samples of all species is 73%.
- Dose coefficients for a reference person as defined by DOE-STD-1196-2011 (DOE 2011) are used; they are for a hypothetical person representing an aggregate of individuals in the U.S. population.
- The entire committed dose is considered to be received during the calendar year.

Dose coefficients (mrem per picocurie [pCi] ingested), based on values listed in DOE-STD-1196-2011, were multiplied by the amount of radioactivity (pCi) potentially ingested to obtain the potential dose (CEDE) (Table 9-2). The average and maximum CEDEs for each monitored location and for each animal species opportunistically sampled are

presented in Table 9-2. Based on the 2014 samples, an individual who consumes one rabbit from each monitored location plus one average mountain lion, mule deer, and pronghorn may receive an estimated 0.65 mrem (0.0065 mSv) dose. To put this dose in perspective, the dose from naturally occurring cosmic radiation received during a 2-hour airplane flight at 39,000 feet is about 1 mrem (0.01 mSv). If a person were to consume the one mule deer with the highest dose (NNSS7-128, see Chapter 8, Table 8-6), they would receive a dose of about 3.2 mrem (0.032 mSv).

Table 9-2. Hypothetical CEDE from ingesting game animals sampled in 2014

CEDE from consuming one animal from each location = 0.65 mrem (using averages) and 3.68 mrem (using maximums)

(a) Based on dose coefficients in Appendix A of DOE-STD-1196-2011 for a Reference Person
 (b) Based on assumption that the water content of all muscle tissue samples is 73%
 (c) Analysis not performed due to insufficient quantity of sample material
 (d) Based on tritium concentration in mountain lion scat

It is possible for someone to consume animals from locations on the NNSS other than where samples were collected in 2014; therefore, Table 9-3 presents the hypothetical CEDE for humans consuming various species of wildlife from a larger number of locations on the NNSS based on animals sampled from 2001 through 2014. The two dose columns show bounding estimates. The first (CEDE High Estimate) is based on eating the number of animals equal to the State possession limit, and the second CEDE is based on eating just one animal. Eating one animal from the NNSS is a more realistic assumption, but including large numbers of animals consumed ensures an understanding of a worst-case scenario.

The average CEDE from consuming just one average animal of a species ranges from 0.0028 mrem (0.000028 mSv) for mourning doves to 0.217 mrem (0.00217 mSv) for mule deer (Table 9-3, last column). The highest CEDE overall for any one species and location is 5.1 mrem (0.051 mSv) from consuming 20 jackrabbits from Plutonium Valley. This represents 5.1% of the annual dose limit for members of the public. The highest dose from consuming just one animal (3.23 mrem or 0.0323 mSv) would be from the mule deer sampled from location Area 19/NNSS7-128 in 2014 (Table 9-2). This is about three times the dose one would receive from naturally occurring cosmic radiation during a 2-hour airplane flight at 39,000 feet. If an individual were to consume one animal of each species with the average concentrations shown in Table 9-3, they would receive an estimated 0.44 mrem/yr (0.0044 mSv/yr) dose.

Average					0.082	0.082
CEDE from consuming one of each game species that has the average dose for that species = 0.44 mrem						

- (a) Sample size is the number of animal samples used to estimate dose.
- (b) Cottontail rabbits and jackrabbit were combined during 2013 for the Palanquin Crater location so dose estimates from these species are the same.
- (c) Samples were composites of kangaroo rats and antelope ground squirrels used as analogs for cottontail rabbits.
- (d) Samples were composites of kangaroo rats and antelope ground squirrels used as analogs for jackrabbits.
- (e) This location is labeled Palanquin Control in the Nevada Test Site Environmental Report 2003 (BN 2004).
- (f) 13 scat samples from a single radio-collared mountain lion (NNSS7).

9.1.1.3 Dose from Ingestion of Plants from the NNSS

Current NNSS land use practices discourage the harvest of plants or plant parts for direct consumption by humans. However, it is possible that individuals with access might collect and consume edible plant material. One species in particular, the pinyon pine tree, produces pine nuts that are harvested and consumed across the western United States. Pinyon pine trees grow throughout regions of higher elevation on the NNSS. During 2013, pine nuts were sampled from three locations on the NNSS (Area 15, Area 17, and in Area 12 near the E Tunnel Ponds). The estimated dose from consuming them was shown to be extremely low (0.00056 mrem or 0.000056 mSv) and a negligible contribution to the total potential dose to a member of the public (NSTec 2014) No other edible plant materials have been collected for analysis on the NNSS in recent history, and no edible plants were sampled in 2014.

9.1.1.4 Dose from Drinking Contaminated Groundwater

The 2014 groundwater monitoring data indicate that groundwater from offsite private and community wells and springs has not been impacted by past NNSS nuclear testing operations (see Sections 5.1.3.5 and 7.2). No man-made radionuclides have been detected in any sampled wells accessible to the offsite public or in sampled private wells or springs. These field monitoring data also agree with the forecasts of current groundwater flow and contaminant transport models discussed in Chapter 11 (see Section 11.1). Therefore, drinking water from underground aquifers containing radionuclides is not a possible pathway of exposure to the public residing off site.

9.1.1.5 Dose from Direct Radiation Exposure along NNSS Borders

The direct exposure pathway from gamma radiation to the public is monitored annually (see Chapter 6). In 2014, the only place where the public has the potential to be exposed to direct radiation from NNSS operations is at Gate 100, the primary entrance to the site on the southern NNSS border. Trucks hauling radioactive materials, primarily low-level waste (LLW) being shipped for disposal at the Area 5 RWMS, park outside Gate 100 while waiting for entry approval. Only during these times is there a potential for exposure to the public due to NNSS activities.

However, no member of the public resides or remains full-time at the Gate 100 truck parking area. Therefore, dose from direct radiation is not included as a possible pathway of exposure to the public residing off site.

9.1.2 Dose from Waste Operations

DOE M 435.1-1 states that LLW disposal facilities shall be operated, maintained, and closed so that a reasonable expectation exists that annual dose to members of the public shall not exceed 10 mrem through the air pathway and 25 mrem through all pathways for a 1,000-year compliance period after closure of the disposal units. Given that the RWMSs are located well within the NNSS boundaries, no members of the public could access these areas for significant periods of time. However, for purposes of documenting potential impacts, the possible pathways for radionuclide movement from waste disposal facilities are monitored.

During 2014, external radiation from waste operations measured near the boundaries of the Area 3 and Area 5 RWMSs could not be distinguished from background levels at those locations (see Section 6.3.4). Area 3 and Area 5 RWMS operations would have contributed negligible external exposure to a hypothetical person residing near the boundaries of these sites and no dose to the offsite public.

The dose from the air pathway can be estimated from air monitoring results from stations near the RWMSs (see Chapter 4, Figure 4-2). Mean concentrations of radionuclides in air at the Area 3 and Area 5 environmental sampler locations were, at the most, only 5% of their CLs. Scaling this to the 10 mrem dose that the CL represents would be 0.5 mrem (0.0051 mSv) to a hypothetical person residing near the boundaries of the RWMS, and the dose would be much lower to the offsite public. There is no exposure, and therefore no dose, to the public from groundwater beneath waste disposal sites on the NNSS. Groundwater monitoring indicates that no man-made radionuclides have been detected in wells accessible to the offsite public or in private wells or springs (see Sections 5.1.3.5 and 7.2). Also, groundwater and vadose zone monitoring at the Area 3 and Area 5 RWMSs, conducted to verify the performance of waste disposal facilities, have not detected the migration of radiological wastes into groundwater (see Section 10.1.7 and 10.1.8). Based on these results, potential doses to members of the public from LLW disposal facilities on the NNSS from all pathways are negligible.

9.1.3 Total Offsite Dose to the Public from all Pathways

The DOE-established radiation dose limit to a member of the general public from all possible pathways as a result of DOE facility operations is 100 mrem/yr (1 mSv/yr) excluding background radiation, while considering air transport, ingestion, and direct exposure pathways. For 2014, the only plausible pathways of public exposure to man-made radionuclides from current or past NNSS activities included the air transport pathway and the ingestion of game animals and plants. The doses from these pathways are combined below to present an estimate of the total 2014 dose to the maximally exposed individual (MEI) (see Glossary, Appendix B) residing off site.

In the recent past, the MEI for the air pathway was considered to be a hypothetical person residing at the critical receptor station with the highest dose (Schooner). However, in an effort to give a more realistic estimate, the 0.02 mrem/yr (0.0002 mSv/yr) dose estimate for the Gate 510 critical receptor station is now used for the dose estimate for an offsite MEI (see Section 4.1.5). If the offsite MEI is assumed to also eat wildlife from the NNSS, additional dose would be received. The additional dose may be 0.65 mrem (0.0065 mSv) (Table 9-2) or 0.44 mrem (0.0044 mSv) (Table 9-3), depending on the consumption scenario used (Section 9.1.1.2), and it could range up to 3.23 mrem (0.0323 mSv) if one person ate a mule deer having elevated radionuclide concentrations like the mule deer sampled in 2014 at the mountain lion kill site Area 19 / NNSS7-128 (Table 9-2). Based on the higher of these scenarios (3.23 mrem), if all the dose from consuming wildlife were received in one year, the TEDE to this hypothetical MEI from all exposure pathways combined and solely due to NNSA/NFO activities would be 3.25 mrem/yr (0.0325 mSv/yr) (Table 9-4).

Table 9-4. Estimated radiological dose to a hypothetical MEI of the general public from 2014 NNSS operations

Pathway	Dose to MEI		Percent of DOE 100 mrem/yr Limit
	(mrem/yr)	(mSv/yr)	
Air ^(a)	0.02	0.0002	0.02
Water ^(b)	0	0	0
Wildlife ^(c)	3.23	0.0323	3.23
Direct ^(d)	0	0	0
All Pathways	3.25	0.0325	3.25

- (a) Based on annual average concentrations at the compliance station nearest the offsite public (Section 4.1.5, Table 4-8)
- (b) Based on all offsite groundwater sampling conducted by NNSA/NFO to date (Section 5.1)
- (c) Based on consuming one mule deer sampled in 2014 having received the highest known dose (Table 9-2)
- (d) Based on 2014 gamma radiation monitoring data at the NNSS entrance (Section 6.3.1)

The total dose of 3.25 mrem/yr to the hypothetical MEI is 3.25% of the DOE limit of 100 mrem/yr and about 0.90% of the total dose that the MEI receives from natural background radiation (360 mrem/yr [3.6 mSv/yr]) (Figure 9-1). Natural background radiation consists of cosmic radiation, terrestrial radiation, radiation from radionuclides within the composition of the human body (primarily potassium-40), and radiation from the inhalation of naturally occurring radon and its progeny. The cosmic and terrestrial components of background radiation shown in Figure 9-1 were estimated from the annual mean radiation exposure rate measured with a pressurized ion chamber (PIC) at Indian Springs by the CEMP (96.4 milliroentgens per year [mR/yr], rounded to 97 mR/yr; see Chapter 7, Table 7-4). The radiation exposure in air, measured by the PIC in units of mR/yr, is approximately equivalent to the unit of mrem/yr for tissue. The portion of the background dose from the internally deposited, naturally occurring radionuclides and from the inhalation of radon and its daughters were estimated at 31 mrem/yr (0.31 mSv/yr) and 229 mrem/yr (2.29 mSv/yr), respectively (Figure 9-1), using the approximations by the National Council on Radiation Protection and Measurements (2006).

Figure 9-1. Comparison of radiation dose to the MEI from the NNSS and natural background (percent of total)

9.1.4 Collective Population Dose

The collective population dose to residents within 80 km (50 mi) of the NNSS emission sources was not estimated in 2014. DOE approved the discontinuance of reporting collective population dose from NNSS operations after 2004 because it is so low for the NNSS. It has been below 0.6 person-rem/yr for the period from 1992, when it was first calculated and reported to DOE, through 2004 (Figure 9-2). The relatively large increase in collective population dose seen in 1994 in Figure 9-2 was due to two changes. The first was the inclusion of plutonium resuspension in air from soils across all areas of the NNSS instead of from soils from only a few areas of the

NNSS in 1992 and 1993. The second was a large increase in the surrounding population in 1994, as Pahrump's population increased by 7,000 and the population of Tonopah (4,200) was added to the calculation.

DOE recommended that NNSA/NFO should consider reporting collective population dose once again if ever it exceeds 1.0 person-rem/yr (DOE 2004). It will be recalculated when either the radionuclide emissions from NNSS activities or the population within 80 km (50 mi) of the NNSS increase significantly (e.g., $\geq 50\%$), both of which are estimated annually (see Section 1.7 for population estimates).

Figure 9-2. Collective population dose within 80 km (50 mi) of NNSS emission sources from 1992 to 2004

9.1.5 Release of Property Containing Residual Radioactive Material

In addition to discharges to the environment, the release of DOE property containing residual radioactive material is a potential contributor to the dose received by the public. The release of property off the NNSS is controlled. No vehicles, equipment, structures, or other materials can be released from the NNSS for unrestricted public use unless the amount of residual radioactivity on such items is less than the authorized limits. The default authorized limits are specified in the *Nevada Test Site Radiological Control Manual* (Radiological Control Manager's Council 2012) and are consistent with the limits set by DOE O 458.1. These limits are shown in Table 9-5.

All NNSA/NFO contractors use a graded approach for release of material and equipment for unrestricted public use. Items are either surveyed prior to release to the public, or a process knowledge evaluation is conducted to verify that the material has not been exposed to radioactive material or beams of radiation capable of generating radioactive material. In some cases, both a radiological survey and a process knowledge evaluation are performed (e.g., a radiological survey is conducted on the outside of the item, and a process knowledge form is signed by the custodian to address inaccessible surfaces). Items are evaluated/surveyed prior to shipment to the NNSA/NFO property/excess warehouse. All contractors also complete material surveys prior to release and transport to the Area 23 landfill. The only exception is for items that could be internally contaminated; these items are submitted to Waste Generator Services for disposal using one of the facilities that can accept LLW. Excessed items that can be free-released are either donated to interested state agencies, federal agencies, or universities; redeployed to other onsite users; or sold on an auction website.

In 2014, 390 pieces of laboratory equipment, 5 vehicles, and 6 pieces of heavy equipment were released off site to the public by these means. No released items had residual radioactivity in excess of the limits specified in Table 9-5.

In 2014, 500 reels of wire cable were excessed, but the process knowledge evaluation could not confirm that the reels were free of any residual contamination, nor was it feasible to unspool each reel to conduct radiological surveys. The reels were therefore auctioned to a recycling company licensed by the Nuclear Regulatory

Commission to possess radioactive material. The recycling company performed the radiological surveys and were able to release the wire for recycling through their Material Release Program.

Independent verification of radiological surveys and process knowledge evaluations performed by NSTec (the Management and Operating contractor) is achieved through NNSA/NFO program oversight and through audits. DOE O 458.1, which includes the process of releasing property to the public, has been incorporated into the site's Radiological Control Managers' Council Internal Audit Schedule, and DOE O 458.1 audits are scheduled to occur once every three years. The last audit was conducted in 2013. In 2013, NNS property release activities were found to be in compliance with the order.

Table 9-5. Allowable total residual surface contamination for property released off the NNS

Radionuclide	Residual Surface Contamination (dpm/100 cm ²) ^(a)		
	Removable	Average ^(b) (Fixed & Removable)	Maximum Allowable ^(c) (Fixed & Removable)
Transuranics, ¹²⁵ I, ¹²⁹ I, ²²⁶ Ra, ²²⁷ Ac, ²²⁸ Ra, ²²⁸ Th, ²³⁰ Th, ²³¹ Pa	20	100	300

9.2 Dose to Aquatic and Terrestrial Biota

DOE requires that their facilities evaluate the potential impacts of radiation exposure to biota in the vicinity of DOE activities. To assist in such an evaluation, DOE's Biota Dose Assessment Committee developed DOE-STD-1153-2002. This standard established the following radiological dose limits for plants and animals. Dose rates equal to or less than these are expected to have no direct, observable effect on plant or animal reproduction:

- 1 rad/d (0.01 grays per day [Gy/d]) for aquatic animals
- 1 rad/d (0.01 Gy/d) for terrestrial plants
- 0.1 rad/d (1 milligray per day) for terrestrial animals

DOE-STD-1153-2002 also provides concentration values for radionuclides in soil, water, and sediment that are to be used as a guide for determining if biota are potentially receiving radiation doses that exceed the limits. These concentrations are called the Biota Concentration Guide (BCG) values. They are defined as the minimum concentration of a radionuclide that would cause dose limits to be exceeded using very conservative uptake and exposure assumptions.

NNS biologists use the graded approach described in DOE-STD-1153-2002. The approach is a three-step process consisting of a data assembly step, a general screening step, and an analysis step. The analysis step consists of site-specific screening, site-specific analysis, and site-specific biota dose assessment. The following information is required by the graded approach:

- Identification of terrestrial and aquatic habitats on the NNS that have radionuclides in soil, water, or sediment
- Identification of terrestrial and aquatic biota on the NNS that occur in contaminated habitats and are at risk of exposure
- Measured or calculated radionuclide concentrations in soil, water, and sediment in contaminated habitats on the NNS that can be compared to BCG values to determine the potential for exceeding biota dose limits

- Measured radionuclide concentrations in NNSS biota, soil, water, and sediment in contaminated habitats on the NNSS to estimate site-specific dose to biota

A comprehensive biota dose assessment for the NNSS using the graded approach was reported in the *Nevada Test Site Environmental Report 2003* (BN 2004). This dose assessment demonstrated that the potential radiological dose to biota on the NNSS was not likely to exceed dose limits. Data from monitoring air, water, and biota across the NNSS do not suggest that NNSS surface contamination conditions have worsened; therefore, this biota dose evaluation conclusion remains the same for 2014.

9.2.1 2014 Site-Specific Biota Dose Assessment

The site-specific biota dose assessment phase of the graded approach centers on the actual collection and analysis of biota. To obtain a predicted internal dose to biota sampled in 2014, the RESRAD-BIOTA, Version 1.5, computer model (DOE 2004) was used. Maximum concentrations of man-made radionuclides detected in plant and animal tissue (see Table 8-3 in Section 8.3.1 and Table 8-5 in Section 8.3.2) were used as input to the model. External dose was based on the measured annual exposure rate using the maximum quarterly thermoluminescent dosimeter (TLD) measurement made closest to each biota sampling site (see Table 6-1 of Chapter 6), minus the average NNSS background exposure rate (see Table 6-2 of Chapter 6). If the average background exposure rate was higher than the monitored location, then man-made external dose was set to zero. The TLD locations used are shown in Table 9-6.

The 2014 site-specific estimated dose rates to biota were all below the DOE limits for both plants and animals (Table 9-6). The highest internal dose was predicted for plants in Plutonium Valley in Area 11 followed by small mammals at the Area 3 RWMS. External dose accounted for an average of 73% of the total dose over all. Samples from Plutonium Valley and the Area 3 and Area 5 RWMSs were elevated compared with their control sites but they were still much less than dose limits.

Table 9-6. Site-specific dose assessment for terrestrial plants and animals sampled in 2014

Location and Species ^(a)	Nearest TLD Location	Estimated Radiological Dose (rad/d)		
		Internal ^(b)	External ^(c)	Total

			DOE Dose Limit:	0.1

(a) For information on plants and animals sampled, see Chapter 8, Tables 8-3 and 8-5

(b) Based on maximum concentrations of each man-made radionuclide detected in plants and animals sampled at that location

(c) Based on maximum TLD measured exposure rates at or near the sample location, see Chapter 6

9.2.2 Dose Assessment Summary

Radionuclides in the environment from past or present NNSS activities result in a potential dose to the public or biota much lower than dose limits set to protect health and the environment. The estimated dose to the MEI for 2014 was 3.25 rem/yr (0.0325 mSv/yr), which is 3.25% of the dose limit set to protect human health. Dose to biota at the NNSS sites sampled in 2014 were less than 4% of dose limits set to protect plant and animal populations. Based on the low potential doses from NNSS radionuclides, impacts from those radionuclides are expected to be negligible.

Chapter 10: Waste Management

Patrick M. Arnold, Rose C. Denton, Stefan J. Duke, Cirilo C. Gonzales, Sydney J. Gordon, Louis B. Gregory, Dodie M. Haworth, David B. Hudson, Coby P. Moke, Brian D. Moran, Alissa J. Silvas, and Ronald W. Warren

National Security Technologies, LLC

Several federal and state regulations govern the safe management, storage, and disposal of radioactive, hazardous, and solid wastes generated or received on the Nevada National Security Site (NNSS) (see Section 2.5). This chapter describes the waste management operations conducted by Environmental Management of the U.S. Department of Energy, National Nuclear Security Administration Nevada Field Office (NNSA/NFO) and summarizes the activities performed in 2014 to meet all environmental/public safety regulations and to meet the major goals of the program shown below.

Waste Management Goals
Manage and safely dispose of low-level waste (LLW), mixed low-level waste (MLLW), and non-radioactive classified waste/matter, which are generated by NNSA/NFO, other U.S. Department of Energy (DOE) approved generators, or selected U.S. Department of Defense (DoD) operations.
Manage and safely store transuranic (TRU) and mixed transuranic (MTRU) wastes generated on site for eventual shipment to the Waste Isolation Pilot Plant (WIPP) in Carlsbad, New Mexico.
Manage, safely store, and ship hazardous wastes generated on the NNSS to approved treatment/storage/disposal facilities, and treat by open detonation explosive ordnance wastes generated on the NNSS.
Ensure that wastes received for disposal meet NNSS waste acceptance criteria.
Evaluate, design, construct, maintain, and monitor closure covers for radioactive waste disposal units at the Area 3 and Area 5 Radioactive Waste Management Sites (RWMSs).
Manage radiation doses from the Area 3 RWMS and the Area 5 Radioactive Waste Management Complex (RWMC) to the levels specified in DOE Manual DOE M 435.1-1, "Radioactive Waste Management Manual."
Manage and safely dispose of solid/sanitary wastes generated by NNSA/NFO operations.
Manage underground storage tanks (USTs) to prevent environmental contamination.
Ensure that disposal systems meet performance objectives.

10.1 Radioactive Waste Management

The NNSS Radioactive Waste Management facilities include the Area 5 RWMC (see Glossary, Appendix B) and the Area 3 RWMS. They operate as Category II non-reactor nuclear facilities. The Area 5 RWMC (Figure 10-1) is composed of the Area 5 RWMS, the Waste Examination Facility (WEF), and the Hazardous Waste Storage Unit (HWSU), which is discussed in Section 10.2. This Section describes the facilities and processes that comprise the safe receipt, storage, disposal, and disposal unit monitoring of radioactive wastes at the NNSS.

10.1.1 Area 5 RWMS

The Area 5 RWMS is a DOE-owned radioactive waste disposal facility. It encompasses approximately 740 acres (ac), including 200 ac of historical and active disposal cells used for burial of LLW, MLLW, Non-Radiological Classified (NRC) waste, and Non-Radiological Classified Hazardous (NRCH) waste, and 540 ac of land available for future radioactive disposal cells. Waste disposal at the Area 5 RWMS occurred in a 92-ac portion of the site starting in the early 1960s. This "92-Acre Area" (Figure 10-1) consists of 31 disposal cells and 13 Greater Confinement Disposal (GCD) boreholes and was used for disposal of waste in drums, soft-sided containers, large cargo containers, and boxes. The 92-Acre Area was filled and permanently closed in 2011. Closure covers for the

Figure 10-1. The Area 5 RWMC

92-Acre Area were seeded in the fall of 2011 and continue to be monitored and reseeded as necessary to aid the establishment of a successful vegetative cover (see Section 15.4). Four new cells have been developed immediately north and west of the 92-Acre Area and have been receiving wastes since 2010. They include three LLW cells (Cells 19, 20, and 21) and a MLLW cell (Cell 18). All active Area 5 RWMS cells can accept radioactive waste contaminated with regulated polychlorinated biphenyl (PCB) bulk product waste. Cell 18 can accept waste contaminated with PCB remediation waste as well as asbestos-contaminated MLLW. Cells 19 and 20 can accept asbestos-contaminated LLW. All disposal cells that were active in 2014 are shown in Table 10-1. MLLW disposal services are expected to continue at the Area 5 RWMS until the remaining needs of the DOE complex are met.

Disposal Cell 18 is operated under a Resource Conservation and Recovery Act (RCRA) Part B Permit (NEV HW0101), which authorizes the disposal of up to 25,485 cubic meters (m³) (899,994 cubic feet [ft³]) of MLLW and NRCH. In 2014, Cell 18 received 2,518 m³ (88,934 ft³) of MLLW/NRCH totaling 1,338 tons (Table 10-1). A cumulative total of 8,695 m³ (307,047 ft³) of MLLW/NRCH has been disposed in Cell 18 through the end of 2014. Quarterly reports were submitted to the State of Nevada in 2014 to document the weight in tons of MLLW/NRCH disposed each quarter in Cell 18.

In 2014, the Area 5 RWMS received shipments containing a total of 36,045 m³ (1,272,900 ft³) of radioactive waste for disposal (Table 10-1), which included both NRC and NRCH waste. The majority of waste disposed was received from offsite generators. The total number of waste shipments during fiscal year (FY) 2014 (October 1, 2013–September 30, 2014) were reported in an annual transportation report (NNSA/NFO 2015). In 2014, all offsite waste generators delivering MLLW for disposal in Cell 18 that contained regulated quantities of PCBs were issued Certificates of Disposal, as required under the Toxic Substances Control Act (see Section 2.6, Table 2-8).

Table 10-1. Total waste volumes received and disposed at the Area 5 RWMS in calendar year 2014

Waste Type	Disposal Cell(s)	Volume Received and Disposed in m ³ (ft ³)
LLW and NRC	Cells 12,14,16, 17, 19, 20, 21	33,526 (1,183,966)
MLLW and NRCH (includes regulated PCB-contaminated LLW)	Cell 18	2,518 (88,934); 1,338 tons ^(a)
	Total	36,045 (1,272,901)

(a) Fees paid to the State for hazardous waste generated at the NNS and MLLW wastes received for disposal are based on weight

10.1.2 WEF

The operational units of the WEF include the TRU Pad, TRU Pad Cover Building (TPCB), TRU Loading Operations Area, WEF Yard, WEF Drum Holding Pad, Sprung Instant Structure, and the Visual Examination and Repackaging Building. The WEF was used for the staging, characterization, repackaging, and offsite shipment of legacy TRU wastes that had been stored for many years at the NNS. This activity was completed in 2009.

Currently, The TRU Pad and TPCB are authorized for the safe storage of radioactive mixed waste under the current RCRA Permit (NEV HW0101). The TPCB accepts TRU/MTRU waste from NNS generators including the Joint Actinide Shock Physics Experimental Research (JASPER) facility. The TPCB stores the waste until it is characterized for disposal at the WIPP in Carlsbad, New Mexico. In 2014, the TRU waste remaining in storage at the TPCB consisted of two experimental spheres from Lawrence Livermore National Laboratory and 26 standard waste boxes from JASPER.

10.1.3 Area 3 RWMS

Disposal operations at the Area 3 RWMS (Figure 10-2) began in the late 1960s. The Area 3 RWMS consists of seven subsidence craters configured into five disposal cells. Each subsidence crater was created by an underground weapons test. Until July 1, 2006, when the site was placed into inactive status, the site was used for disposal of bulk LLW, such as soils or debris, and waste in large cargo containers. The site consists of the following seven craters:

2 Disposal Cells (Inactive Status):

U-3ah/at
U-3bh

1 Closed Cell:

U-3ax/bl
(Corrective Action Unit 110)

2 Undeveloped Cells:

U-3az
U-3bg

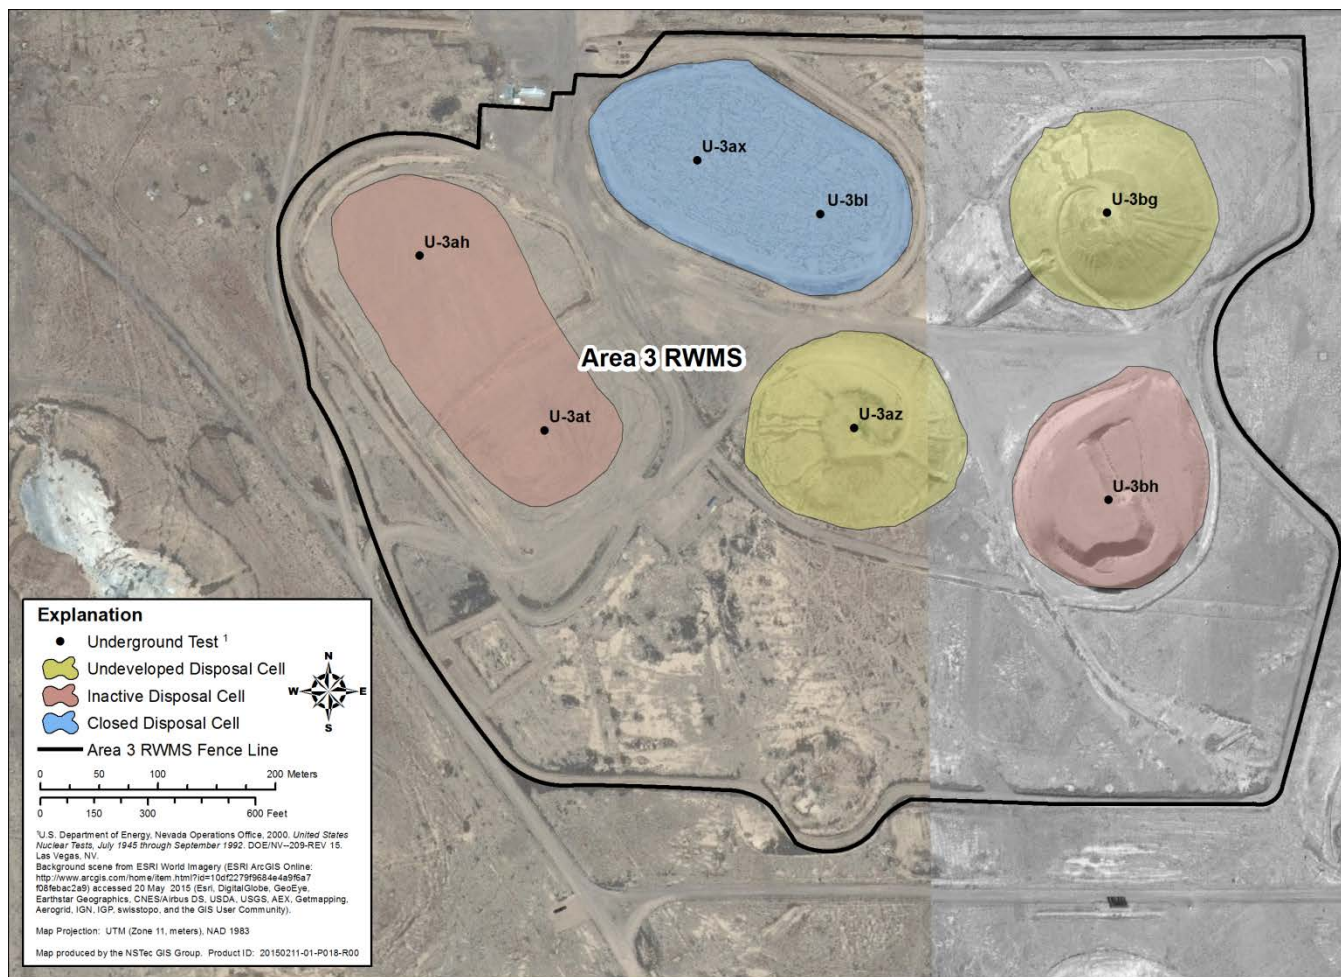

Figure 10-2. The Area 3 RWMS

10.1.4 Waste Characterization

All generators of waste streams must demonstrate eligibility for waste to be disposed at the NNSS, submit profiles characterizing specific waste streams, meet the NNSS Waste Acceptance Criteria, and receive programmatic approval from NNSA/NFO for their site waste certification programs.

Characterization is performed by approved NNSA/NFO waste generators using knowledge of the generating process, sampling and analysis, or non-destructive analysis. Following the characterization of a waste stream, the approved NNSA/NFO waste generator develops a waste profile. The waste profile delineates the pedigree of the waste, including, but not limited to, a description of the waste generating process, physical and chemical characteristics, radioactive isotope activity and quantity, and packaging information. The waste profile is reviewed by the Waste Acceptance Review Panel for eventual approval or disapproval by NNSA/NFO. The approved waste generator then packages and ships approved waste streams in accordance with U.S. Department of Transportation requirements to the Area 5 RWMS or to an offsite facility for treatment, if necessary, prior to its return shipment for disposal at the Area 5 RWMS.

In 2014, LLW and MLLW were characterized by approved waste generators for the following general waste stream categories:

- Lead Solids
- Sealed Sources
- Miscellaneous Debris
- Hazardous Soils
- Contaminated PCB Waste
- Compactable Trash
- Contaminated Soils
- Depleted Uranium
- Contaminated Asbestos Waste
- Non-radioactive Classified Matter/Waste

10.1.5 Verification of Waste Acceptance Criteria

Waste verification is an inspection process that confirms the waste stream data supplied by approved waste generators before MLLW or non-radioactive classified hazardous waste is accepted for disposal at the NNSS. Verification may involve visual inspection, Real-Time Radiography (RTR), and/or chemical screening on a designated percentage of MLLW or non-radioactive classified hazardous waste. The objectives of waste verification include verifying that hazardous waste treatment objectives are met, confirming that waste containers do not contain free liquids, and ensuring that waste containers are at least 90% full, per RCRA and State of Nevada requirements. Offsite-generated waste is verified either when the waste is received at the NNSS or when it is still at a generator facility or a designated treatment, storage, or disposal facility. The first choice for the method of verification is visual inspection at the site of generation.

In 2014, offsite visual inspections were completed on 123 MLLW packages from 19 separate waste streams and on 4 non-radioactive classified hazardous waste packages from 1 waste stream. No RTR or chemical screening was required in 2014. Onsite visual inspection was conducted on one MLLW package in 2014. No MLLW or non-radioactive classified hazardous waste packages were rejected during 2014.

10.1.6 Performance Assessments, Analyses, and Annual Reviews

To assess and predict the long-term performance of NNSS disposal sites, NNSA/NFO conducts a Performance Assessment (PA) and a Composite Analysis (CA). A PA is a systematic analysis of the potential risks posed by a waste disposal facility to the public and to the environment for LLW disposed after 1988. A CA is an assessment of the risks posed by all wastes disposed in a LLW disposal facility and by all other sources of residual contamination that may interact with the disposal site. NNSA/NFO maintains current PAs and CAs for the Area 3 and Area 5 RWMSs (Table 10-2). The *Maintenance Plan for the Performance Assessments and Composite Analyses for the Area 3 and Area 5 Radioactive Waste Management Sites at the NNSS* (National Security Technologies, LLC [NSTec], 2007) requires an annual review to assess the adequacy of the PAs and CAs, and results are submitted annually to the DOE Office of Environmental Management. The Disposal Authorization Statements for the Area 3 and Area 5 RWMSs also require that annual reviews be made and that secondary or minor unresolved issues be tracked and addressed as part of the Maintenance Plan.

In 2014, NNSA/NFO performed an annual review of the Area 3 and Area 5 RWMS PAs and CAs. Operational factors (e.g., waste forms and containers, facility design), closure plans, monitoring results, and research and development activities in or near the facilities were also reviewed. Because the Area 3 RWMS has been in inactive status since July 1, 2006, a special analysis was prepared in FY 2012 to update the PA and CA results for the Area 3 RWMS. The FY 2014 annual summary report to DOE (NSTec 2015a) presented data and conclusions that verified the adequacy of both the Area 3 and Area 5 PAs and CAs. Table 10-2 lists the key documents that must be current and in place for RWMS disposal operations to occur. In 2014, all of these key documents were maintained and one was revised.

10.1.7 Groundwater Monitoring

Disposal Cell 18 is operated according to RCRA standards for the disposal of MLLW. Title 40 Code of Federal Regulations (CFR) Part 265, "Groundwater Monitoring," Subpart F (40 CFR 265.92) requires groundwater monitoring to verify the performance of Cell 18 to protect groundwater from buried hazardous wastes. Wells UE5 PW-1, UE5 PW-2, and UE5 PW-3 are monitored for this purpose. Investigation levels (ILs) for five indicators of groundwater contamination (Table 10-3) were established by NNSA/NFO and the Nevada Division of Environmental Protection (NDEP) for these three wells in 1998. Samples collected semiannually in 2014 from the wells had contaminant levels below their ILs (Table 10-3). Static water levels and general water chemistry parameters are also monitored. All sample analysis results are presented in NSTec (2015b). Table 5-4 of Section 5.1.2 presents the tritium results for each water sample collected in 2014 from UE5 PW-1, UE5 PW-2, and UE5 PW-3.

Table 10-3. Results of groundwater monitoring of UE5 PW-1, UE5 PW-2, and UE5 PW-3 in 2014

Parameter	Investigation Level (IL)	Sample Levels ^(a)
pH	< 7.6 or > 9.2 S.U. ^(b)	8.22 to 8.36 S.U.
Specific conductance (SC)	0.440 mmhos/cm ^(c)	0.331 to 0.381 mmhos/cm
Total organic carbon (TOC)	1 mg/L ^(d)	<0.33 to 0.35 mg/L
Total organic halides (TOX)	50 µg/L ^(e)	<3.3 to 3.7 µg/L
Tritium (³ H)	2,000 pCi/L ^(f)	-5.09 to 16.7 pCi/L

(a) Levels shown are the lowest and highest values of the averages for each well for each sample date.

Source: NSTec (2014b)

(b) S.U. = standard unit(s) (for measuring pH)

(c) mmhos/cm = millimhos per centimeter

(d) mg/L = milligrams per liter

(e) µg/L = microgram(s) per liter

(f) pCi/L = picocuries per liter

10.1.8 Vadose Zone Monitoring

Monitoring of the vadose zone (unsaturated zone above the water table) is conducted at the RWMC to demonstrate that (1) the PA assumptions at the RWMSs are valid regarding the hydrologic conceptual models used, including soil water contents, and upward and downward flux rates and (2) there is negligible infiltration and percolation of precipitation into zones of buried waste at the RWMSs. Vadose zone monitoring (VZM) offers many advantages over groundwater monitoring, including detecting potential problems long before groundwater resources would be impacted, allowing corrective actions to be made early, and being less expensive than groundwater monitoring. The components of the VZM program include the Drainage Lysimeter Facility northwest of U-3ax/bl, the Area 5

Weighing Lysimeter Facility southwest of the Area 5 RWMS, two meteorology towers, and eight nests of instruments in five waste disposal cell covers that measure water content and water potential profiles in the covers. Data from all of these components are used to monitor the natural water balance at the RWMSs. Descriptions of the VZM components and the results of monitoring in 2014 are reported in NSTec (2015c). All VZM results in 2014 continued to demonstrate that there is negligible infiltration of precipitation into zones of buried waste at the RWMC and that the performance criteria of the waste disposal cells are being met to prevent contamination of groundwater and the environment.

10.1.9 Assessment of Radiological Dose to the Public

DOE M 435.1-1 states that LLW disposal facilities shall be operated, maintained, and closed so that a reasonable expectation exists that annual dose to members of the public shall not exceed 10 millirem (mrem) through the air pathway and 25 mrem through all pathways for a 1,000-year compliance period after closure of the disposal units. Given that the RWMSs are located well within the NNSS boundaries, no members of the public can currently access these areas for significant periods of time to acquire a dose exceeding the 10 or 25 mrem annual limit. To document compliance with DOE M 435.1-1, however, the possible pathways for radionuclide movement from waste disposal facilities are monitored. Long-term compliance with the DOE M 435.1-1 dose limits is evaluated by performance assessment modeling.

10.1.9.1 Dose from Air and Direct Radiation

Air samplers operate continuously to collect air particulates and atmospheric moisture near each RWMS. These samples are analyzed for radionuclides, and results are used to assess potential dose. Details of the air sampling and a summary of the analysis results can be found in Chapter 4. In 2014, three environmental sampling stations operated in/near the Area 3 RWMS (U-3ax/bl S, Bilby Crater, and Kestrel Crater N), and two air monitoring stations operated near the Area 5 RWMS (DoD and RWMS 5 Lagoons). The dose from the air pathway was estimated based on the highest annual mean concentration results for each measured radionuclide from among these five stations in order to estimate a worst-case dose for a member of the public at either of the RWMSs.

The highest annual mean concentration of each measured radionuclide among the five stations, and the station at which the highest concentration occurred, are shown in Table 10-4. The highest concentration of any radionuclide was 3,180 microcuries per milliliter ($\mu\text{Ci}/\text{mL}$) for ^3H at RWMS 5 Lagoons. All four of the highest mean concentrations shown in Table 10-4 were far below their established National Emission Standards for Hazardous Air Pollutants (NESHAP) Concentration Levels for Environmental Compliance (CLs) (Table 10-4, fourth column). The highest mean concentration of each measured radionuclide is divided by its respective CL to obtain a “fraction of CL” (Table 10-4, right-most column). The fractions are then summed, and if the sum is less than 1, it demonstrates that the NESHAP dose limit of 10 mrem/yr was not exceeded at a location having all those radionuclides at those concentrations. Summing the fractions of CLs gives 0.05, which is only 5% of the limit in this worst-case scenario. Scaling this to the 10 mrem dose that the CLs represent would mean that a hypothetical person residing near the RWMS would receive an annual dose of about 0.5 mrem/yr from the air pathway.

Table 10-4. Highest annual mean concentrations of radionuclides detected in 2014 at Area 3 and Area 5 RWMS

Radionuclide	RWMS Sampler with Highest Concentration	Highest Annual Mean Concentration ($\times 10^{-15} \mu\text{Ci}/\text{mL}$)	NESHAP CL ^(a) ($\times 10^{-15} \mu\text{Ci}/\text{mL}$)	Fraction of CL
^{241}Am	U-3ax/bl S	0.0119	1.9	0.006
^3H	RWMS 5 Lagoons	3,180	1,500,000	0.002
^{238}Pu	Kestrel Crater N	0.00262	2.1	0.001
^{239}Pu	U-3ax/bl S	0.0794 ($^{239+240}\text{Pu}$)	2	0.040
Sum of Fractions:				0.049

Note: The CL values represent an annual average concentration that would result in a total effective dose equivalent of 10 mrem/yr, the federal dose limit to the public from all radioactive air emissions.

(a) From Table 2, Appendix E of 40 CFR 61, “National Emission Standards for Hazardous Air Pollutants,” 1999.

Thermoluminescent dosimeters (TLDs) are used to measure ionizing radiation exposure at 5 locations in and around the Area 3 RWMS and 12 locations in and around the Area 5 RWMS. The TLDs have three calcium sulfate elements used to measure the total exposure rate from penetrating gamma radiation, including background radiation. The penetrating gamma radiation makes up the deep dose, which is compared to the 25 mrem/yr limit when background exposure is subtracted. Details of the direct radiation monitoring can be found in Chapter 6. During 2014, the external radiation measured near the boundaries of the Area 3 and Area 5 RWMSs could not be distinguished from background levels (see Section 6.3.4). Area 3 and Area 5 RWMS operations would have contributed negligible external exposure to a hypothetical person residing near the boundaries of these sites and no dose to the offsite public.

10.1.9.2 Dose from Groundwater

Groundwater and vadose zone monitoring at the RWMSs is conducted to verify the performance of waste disposal facilities. Such monitoring has not detected the migration of radiological wastes into groundwater (see Sections 10.1.7 and 10.1.8). Also, the results of monitoring offsite public and private wells and springs indicate that man-made radionuclides have not been detected in any public or private water supplies (see Table 5-4, Section 5.1.2, and Section 7.2). Based on these results, potential doses to members of the public from LLW disposal facilities on the NNSS from groundwater, and from all pathways combined, are negligible.

10.2 Hazardous Waste Management

Hazardous waste regulated under RCRA is generated at the NNSS from a broad range of activities, including onsite laboratories, site and vehicle maintenance, communications operations, and environmental restoration of historical contaminated sites (see Chapter 11). The RCRA Part B Permit NEV HW0101 regulates the operation of the Area 5 Mixed Waste Disposal Unit (or Cell 18), the Hazardous Waste Storage Unit (HWSU), and the Explosive Ordnance Disposal Unit (EODU) facilities. Included in the RCRA Part B permit is authorization for the storage of MLLW at the Mixed Waste Storage Unit (MWSU), which comprises the following four facilities at the Area 5 RWMC: the TPCB and TRU Pad, the Sprung Instant Structure Building, the Visual Examination and Repackaging Building, and the Drum Holding Pad.

The HWSU (Figure 10-1) is a pre-fabricated, rigid-steel-framed, roofed shelter that is permitted to store a maximum of 61,600 liters (16,280 gallons) of approved waste at a time. Hazardous waste generated at NNSA/NFO environmental restoration sites off the NNSS (e.g., at the Tonopah Test Range) or generated at the North Las Vegas Facility are direct-shipped to approved disposal facilities. Hazardous waste generated on the NNSS is also direct-shipped from sites on the NNSS (i.e., not from the HWSU) if the sites generate bulk, non-packaged hazardous waste that is not accepted at the HWSU for storage. Hazardous waste would also be direct-shipped from NNSS sites in the unlikely case when the waste volume capacity of the HWSU is approaching its permitted limits. Satellite Accumulation Areas (SAAs) and 90-day Hazardous Waste Accumulation Areas (HWAAs) are used at the NNSS for the temporary storage of hazardous waste prior to direct shipment off site or to the HWSU.

The EODU is permitted to treat explosive ordnance wastes by open detonation of not more than 45.4 kilograms (100 pounds) of approved waste at a time, not to exceed one detonation event per hour. Conventional explosive wastes are generated at the NNSS from explosive operations at construction and experiment sites, the NNSS firing range, the resident national laboratories, and other activities.

10.2.1 2014 Hazardous Waste Activities

The RCRA permit requires preparation of a U.S. Environmental Protection Agency Biennial Hazardous Waste Report of all hazardous waste volumes generated and disposed or stored at the NNSS. This report is prepared for odd-numbered years only. It was last prepared for 2013 and submitted to the State of Nevada in February 2014. The next biennial report will be prepared for 2015 and submitted to the State in 2016. An annual waste volume report was prepared in 2014 and submitted to the State of Nevada in February 2015 (NSTec 2015d). It includes the amount of wastes received in calendar year 2014 at the Area 5 MWSU, HWSU, EODU, and Cell 18.

Table 10-5 presents the quantities of hazardous waste either generated on or off site that were managed (received, stored, shipped, or disposed) at the various NNSS waste units during calendar year 2014. It includes the tons of MLLW received and disposed on site in Cell 18; the tons of MLLW received at the MWSU; the tons of MLLW shipped off site from the MWSU for disposal; the tons of hazardous waste with and without PCBs received, stored, and shipped off site from the HWSU; and the tons of hazardous waste stored and then shipped off site from one or more HWAAAs. In 2014, no hazardous waste was direct-shipped from NNSS SAAs. Quarterly 2014 hazardous waste volume reports were submitted on schedule to NDEP.

No waste explosive ordnance were detonated at the EODU in 2014.

Table 10-5. Hazardous waste managed at the NNSS in 2014

Unit	Amount Received (tons) ^(a)	Amount Shipped (tons)	Amount Disposed (tons)
Cell 18	1,338	0	1,338
MWSU	0.29	0.75	--
HWSU	8.94	7.67	--
HWSU – PCB Waste	2.41	2.18	--
HWAA	NA ^(b)	10.83	--
EODU	0	0	--

(a) Fees paid to the State for H W generated at the NNSS and MLLW wastes received for disposal are based on weight (tons)

(b) Not applicable; amounts of HW received at HWAAAs are not tracked, only the length of time they are stored and the amounts shipped off from all HWAAAs combined are tracked.

10.3 *Underground Storage Tank (UST) Management*

RCRA regulates the storage, transportation, treatment, and disposal of hazardous wastes to prevent contaminants from leaching into the environment from USTs. Nevada Administrative Code NAC 459.9921–459.999, “Storage Tanks,” enforces the federal regulations under RCRA pertaining to the maintenance and operation of USTs and the regulated substances contained in them so as to prevent environmental contamination. NNSA/NFO operates one deferred UST and three excluded USTs at the Device Assembly Facility; one fully regulated UST at the Area 6 Helicopter pad, which is not in service; and three fully regulated USTs, one deferred UST, and three excluded USTs at the Remote Sensing Laboratory–Nellis (RSL-Nellis). NDEP has oversight authority of the NNSS USTs, and the Southern Nevada Health District has oversight authority of USTs in Clark County (see Appendix A, Section A.2.3 regarding UST management at RSL-Nellis). NDEP usually conducts inspections of NNSS USTs once every 3 years. No inspections were conducted in 2014 since they were last conducted in 2013. In 2014, no NNSS USTs were upgraded or removed.

10.4 *Solid and Sanitary Waste Management*

Three landfills for solid waste disposal were operated at the NNSS in 2014. The landfills are regulated and permitted by the State of Nevada (see Table 2-13 for list of permits). No liquids, hazardous waste, or radioactive waste are accepted in these landfills. They include:

- Area 6 Hydrocarbon Disposal Site – accepts hydrocarbon-contaminated wastes, such as soil and absorbents.
- Area 9 U10c Solid Waste Disposal Site – designated for industrial waste such as construction and demolition debris and asbestos waste under certain circumstances.
- Area 23 Solid Waste Disposal Site – accepts municipal-type wastes such as food waste and office waste. Regulated asbestos-containing material is also permitted in a special section. The permit allows disposal of no more than an average of 20 tons/day at this site.

These landfills are designed, constructed, operated, maintained, and monitored in adherence to the requirements of their state-issued permits. NDEP visually inspects the landfills and checks the records on an annual basis to ensure compliance with the permits. No non-compliance issues were noted during the 2014 NDEP inspection. The amount of waste disposed in each solid waste landfill is shown in Table 10-6.

The vadose zone is monitored at the Area 6 Hydrocarbon Disposal Site and the Area 9 U10c Solid Waste Disposal Site. VZM is performed once annually in lieu of groundwater monitoring to demonstrate that contaminants from the landfills are not leaching into the groundwater. VZM in 2014 indicated that there was no soil moisture migration and, therefore, no waste leachate migration to the water table.

Table 10-6. Quantity of solid wastes disposed in NNSS landfills in 2014

Waste Disposed in Landfills in Metric Tons (Tons)		
Area 6	Area 9	Area 23
4.3 (4.7)	559 (616)	750 (827)

Environmental Restoration (ER) evaluates and implements corrective actions on those portions of the Nevada National Security Site (NNSS), the Nevada Test and Training Range (NTTR), and the Tonopah Test Range (TTR) that have been impacted by atmospheric and underground nuclear tests conducted from 1951 to 1992. These sites are referred to as corrective action sites (CASs). ER is the responsibility of Environmental Management (EM) of the U.S. Department of Energy, National Nuclear Security Administration Nevada Field Office (NNSA/NFO). Cleanup strategies and corrective actions are developed based on the nature and extent of contamination and the risks posed by that contamination. ER is responsible for approximately 3,000 CASs in Nevada.

CASs are broadly organized into four categories based on the source of contamination: Underground Test Area (UGTA) sites, Industrial sites, Soils sites, and Nevada Offsites. Multiple CASs are grouped into corrective action units (CAUs) according to location, physical and geological characteristics, and/or contaminants. UGTA is the largest component of NNSA/NFO's EM Operations and includes five CAUs of 878 CASs that are directly related to the geographical areas of past underground nuclear testing. Industrial sites are facilities and land that may have become contaminated as a result of activities conducted in support of nuclear testing, and include disposal wells, inactive tanks, contaminated waste sites, inactive ponds, muck piles, spill sites, drains and sumps, and ordnance sites. Soils sites include areas where nuclear tests have resulted in extensive surface and/or shallow subsurface contamination that include radioactive materials as well as possibly oils, solvents, heavy metals, and contaminated instruments and test structures used during testing activities. Nevada Offsites are associated with underground nuclear testing at the Project Shoal Area and the Central Nevada Test Area, located in northern and central Nevada, respectively. Nevada Offsites are managed by the U.S. Department of Energy (DOE) Office of Legacy Management.

In April 1996, the DOE, the U.S. Department of Defense, and the State of Nevada entered into a Federal Facility Agreement and Consent Order (FFACO) to address the environmental restoration of CASs. Appendix VI of the FFACO (as amended), describes the strategy that will be employed to plan, implement, and complete environmental corrective actions (i.e., to "close" the CASs). ER activities follow a formal work process described in the FFACO. The State of Nevada is a participant throughout the closure process, and the Nevada Site Specific Advisory Board (NSSAB) is kept informed of the progress made. The NSSAB is a formal volunteer group of interested citizens and representatives who provide informed recommendations to NNSA/NFO EM. The NSSAB's comments are strongly considered throughout the corrective action process. This section summarizes actions taken by ER towards the closure of UGTA, Industrial, and Soils sites in 2014.

Environmental Restoration Objectives for All Sites

Characterize sites contaminated by NNSA/NFO nuclear testing activities.

Remediate contaminated sites in accordance with FFACO-approved planning documents.

Conduct post-closure monitoring of sites in accordance with FFACO closure documents.

11.1 UGTA Sites

From 1951 to 1992, more than 800 underground nuclear tests, some involving multiple detonations, were conducted at the NNSS (U.S. Department of Energy, Nevada Operations Office [DOE/NV] 2000). Most were

conducted hundreds of feet above groundwater; however, over 200 were within or near the water table. The test locations (i.e., CASs) are grouped into five CAUs based primarily on geographically distinct areas of underground testing (Figure 11-1). Closure-in-place with institutional controls (e.g., restricting land and groundwater access) and monitoring is considered to be the only feasible corrective action for these sites because cost-effective groundwater technologies have not been developed to effectively remove or stabilize deep subsurface radiological contaminants.

Corrective actions for each CAU begin with data collection and analysis activities, called characterization studies. In addition, water levels, which are routinely measured in wells throughout the NNSS and surrounding area, are evaluated to determine groundwater flow directions (e.g., Fenelon et al. 2010) (Figure 11-2). The characterization studies, NNSS water-level monitoring data, and regional three-dimensional groundwater flow models (International Technology Corporation 1996; Belcher and Sweetkind 2010) provide the basis for developing models of the hydrogeologic setting, the radiological source term, and flow and contaminant transport for each CAU. The spatial extent of these models for each CAU is presented in Figure 11-3. The numerous surface and subsurface investigations and computer modeling conducted for UGTA CAUs are performed by various participating organizations including National Security Technologies, LLC (NSTec); Los Alamos National Laboratory (LANL); Lawrence Livermore National Laboratory (LLNL); the U.S. Geological Survey (USGS); the Desert Research Institute (DRI); and Navarro.

The groundwater flow and contaminant transport models will ultimately be used to design monitoring well networks and land use restrictions that protect the public. For four of the five UGTA CAUs, these models will be used to identify contaminant boundaries that forecast areas that potentially could exceed the Safe Drinking Water Act (SDWA) maximum contaminant levels for radionuclides over the next 1,000 years. Such contaminant boundary forecasts are not required by the FFACO for the Rainier Mesa/Shoshone Mountain CAU due to the determination that field data are, and will be, insufficient to develop models which could reliably identify a contaminant boundary in this geologically complex area (NNSA/NFO 2013). For this CAU, the models must instead demonstrate that institutional controls will not be challenged by radionuclides originating from underground tests conducted in the CAU within the 1,000-year compliance period.

As required under the FFACO, once characterization activities and model development have been completed, the following items will be sequentially identified/defined for each CAU in agreement between DOE and the Nevada Division of Environmental Protection (NDEP): a regulatory boundary objective statement, regulatory boundary(ies), and use-restriction boundaries. UGTA corrective actions for all CAUs are expected to be completed by fiscal year (FY) 2030 (October 1, 2029–September 30, 2030).

Environmental Restoration Objectives for UGTA Sites

Develop a regional three-dimensional computer groundwater model to identify immediate risks and provide a basis for developing more detailed CAU-specific models.

Develop CAU-specific models of groundwater flow and contaminant transport that geographically cover the five former NNSS underground nuclear testing areas.

Identify contaminant boundaries^(a) (which support regulatory decision-making processes) where contaminants are forecasted to exceed the SDWA limits at any time within a 1,000-year compliance period.

Negotiate regulatory objectives and regulatory boundaries to protect the public and environment from the effects of radioactive contaminant migration.

Negotiate use-restriction boundaries to restrict access to contaminated groundwater.

Develop a long-term closure monitoring network to verify consistency with the flow and transport models, compliance to the regulatory boundary, and protection of human health and the environment.

^(a) The identification of contaminant boundaries are objectives for all UGTA CAUs except for the Rainier Mesa/Shoshone Mountain CAU, for which it must be demonstrated that institutional controls will not be challenged by radionuclides from underground tests conducted in the CAU within the 1,000-year compliance period.

11.1.1 UGTA CAU Corrective Action Activities

The UGTA CAU closure strategy is a process of conducting characterization and modeling studies during the *investigation stage* to support 1,000-year contaminant boundary forecasts. Sufficient confidence in the flow and transport models and supporting data must be demonstrated to earn NDEP's approval to advance from the investigation stage to the *model evaluation stage* and then to the *closure stage* for each CAU. The long-term monitoring program and institutional controls to protect the public from consuming potentially contaminated groundwater are initiated in the closure stage. The five UGTA CAUs are in various stages of this process. The following subsections provide a brief history of the actions taken to date towards the closure-in-place of each CAU. The results of groundwater sampling conducted in 2014, for the purposes of characterizing groundwater within the CAUs and monitoring groundwater downgradient of them, are presented and discussed in Chapter 5, Sections 5.1.2 and 5.1.3.

11.1.1.1 Frenchman Flat CAU

The Frenchman Flat CAU is the first of the five UGTA CAUs at the NNSS to complete a formal independent peer review for the CAU flow and transport model and supporting data and investigations. In 2010, the Phase II Transport Model was published (Navarro Nevada Environmental Services, LLC, 2010). NDEP approved the Frenchman Flat flow and transport model, and the external peer review panel recommended advancement to the next stage in the closure process (N-I 2010). In 2011, a Corrective Action Decision Document/Corrective Action Plan (CADD/CAP) was prepared to describe the path forward for evaluating the groundwater flow and transport models. Initial use-restriction boundaries and a Regulatory Boundary Objective were established and presented in the CADD/CAP (U.S. Department of Energy, National Nuclear Security Administration Nevada Site Office [NNSA/NSO] 2011a). The CADD/CAP was approved by NDEP in 2011.

A model evaluation drilling program was initiated and completed in 2012 as part of the CADD/CAP. Two model evaluation wells, ER-5-5 and ER-11-2, were drilled near two underground nuclear test cavities (N-I 2012), and well development, hydrologic testing, and sampling were conducted in 2013 (N-I 2014a). New data were compared to the existing models and model forecasts. The data indicate that the local geology disrupts the flow path of contaminants away from the Pin Stripe nuclear test cavity (borehole U-11b) near ER-11-2, and that the test cavity is no longer considered a source of radionuclide contamination to ER-11-2 groundwater. Therefore, ER-11-2 was dropped from the sampling network and the contaminant boundary associated with the Pin Stripe test was revised. Well ER-5-5, drilled near the Milk Shake nuclear test cavity (borehole U-5k), is currently classified as a Characterization well within the network (see Table 5-4, Section 5.1.2, Chapter 5).

As part of the model evaluation stage, new survey (geospatial location), geology, aquifer test, and water-level data were evaluated by the Frenchman Flat modeling team, and a series of reviews were performed by a panel of experts (preemptive review committee). In 2014, the flow and transport model evaluation was completed and the modeling team and preemptive review committee agreed that there is sufficient confidence in the Frenchman Flat model to advance to the closure stage. The model evaluation report (N-I 2014a) was accepted by NDEP and the Frenchman Flat CAU was approved in 2014 to move to the closure stage. Following approval, DOE and NDEP began discussions regarding the development and implementation of a monitoring program and identification of final use-restriction and regulatory boundaries. Once finalized, this information will be presented in the Closure Report.

11.1.1.2 Central and Western Pahute Mesa CAUs

The Central and Western Pahute Mesa CAUs are in the middle of the investigation stage of the closure process. In 2009, a Phase I Central and Western Pahute Mesa Transport Model (Stoller-Navarro Joint Venture 2009) was completed for the Pahute Mesa–Oasis Valley model area. An additional phase of data collection and model development (Phase II) was needed in order to establish the necessary confidence to move forward with the closure process. Phase II data collection activities were recommended by an ad hoc subcommittee that included the NNSA/NFO UGTA Federal Activity Lead, UGTA participants (NSTec, DRI, LLNL, LANL, Navarro, and USGS), a representative from NDEP, and two representatives of the NSSAB.

A Phase II Central and Western Pahute Mesa Corrective Action Investigation Plan (CAIP) was completed in 2009 (NNSA/NSO 2009) that outlines the field investigation program that is currently being implemented. The program's

objective is to institute a second phase of data collection to test the assumptions of the Phase I groundwater flow and contaminant transport models, improve the quality of data used in the models, and increase confidence in the transport model results used to forecast contaminant boundaries. Twelve locations for new wells were proposed, ten of which were selected for drilling. Phase II drilling began in May 2009 and was completed in 2012. Development, testing, and sampling the ten Phase II wells was completed in May 2014.

The Phase I Central and Western Pahute Mesa Transport Model forecasts that tritium and carbon-14 may migrate off the NNSS from the Central and Western Pahute Mesa CAUs within 50 years of the first nuclear detonation (1965) and that offsite concentrations of tritium may be above the SDWA limit of 20,000 pCi/L within the 1,000-year compliance period (Figure 11-4). Consistent with this flow and transport model forecast, tritium was detected at 10,600 pCi/L in Well ER-EC-11 on the NTTR in 2009 (NSTec 2010). It is the first offsite well in which radionuclides from underground nuclear testing activities at the NNSS were detected. Well ER-EC-11 is located approximately 716.3 m (2,350 ft) west of the NNSS boundary (see Figure 5-2, Chapter 5) and approximately 3.2 km (2 mi) from the nearest underground nuclear tests, Benham and Tybo, which were conducted in 1968 and 1975, respectively. In 2014, samples were collected from the same aquifer where high tritium was previously reported using a newly available technology. The maximum tritium concentration measured in these samples was 16,100 pCi/L (see Table 5-4, Section 5.1.2, Chapter 5). Because this sample was collected after purging several well volumes from the well, it is considered more representative of the shallow groundwater at ER-EC-11 than those bailed during the drilling operation and reported in 2009.

Tritium detected in Well ER-20-11 (see Table 5-4, Chapter 5) is believed to represent the downgradient extension of the Benham-Tybo contaminant plume. This contaminant plume was first encountered at ER-20-5 (DOE/NV 1997) and further defined by Well ER-20-7 (NNSA/NSO 2010a) and peripheral Wells ER-EC-11 (NNSA/NSO 2010b) and ER-20-8/20-8#2 (NNSA/NSO 2011b). This cluster of contaminated wells is increasing the understanding of flow and transport of radionuclides from underground tests on Pahute Mesa. The discovery of tritium at Well ER-20-11 indicates that the contaminant plume forecasted by Phase I flow and transport modeling may be more southerly (ER-20-5 to ER-20-7 to ER-20-11) than previously modeled. Phase II flow and transport modeling will include the new data from the Phase II drilling initiative and will reflect the recent tritium measurements.

As part of the Phase II activities at Pahute Mesa, the Phase I hydrostratigraphic framework model (BN 2002) was rebuilt in 2013. This new model incorporates new Phase II data from the 10 additional characterization wells. Other refinements include subdividing composite units (hydrostratigraphic units composed of both aquifers and non-aquifers) into their respective hydrogeologic components. A draft documentation report for the Phase II hydrostratigraphic framework model was completed and disseminated for preemptive review in 2014 and is expected to be finalized in 2015.

In 2014, analysis of faults and fracture characteristics and of hydraulic properties of selected hydrostratigraphic units continued. These studies are still in progress; however to date, this information is being used to enhance conceptual models for the Phase II hydrostratigraphic framework model as well as to provide attributes for specific aquifers on and immediately downgradient of Pahute Mesa. Additional characterization activities performed in 2014 include groundwater sampling, measuring water levels, and a variety of analyses tasks to evaluate the Phase II geologic, hydrologic, and chemistry data.

11.1.1.3 Rainier Mesa/Shoshone Mountain CAU

The Rainier Mesa/Shoshone Mountain CAU is near the end of the investigation stage of the closure process. In 2007, the hydrogeologic model for this CAU was completed (NSTec 2007) and in 2013, the draft groundwater flow and contaminant transport models were completed. The ensemble of models was subjected to several cycles of preemptive reviews and summary presentations to NDEP. Compilation of attendant data packages and writing of the draft flow and transport model document were completed in 2013. Efforts to develop a more robust conceptual model for the unsaturated zone began in 2013 and will be included in the final flow and transport model documentation. To facilitate this effort, the initial hydrostratigraphic framework model (NSTec 2007) was rebuilt. This rebuild effort began in late 2013 and was completed in 2014.

Figure 11-4. Results of Phase I Central and Western Pahute Mesa Transport Modeling

11.1.1.4 Yucca Flat/Climax Mine CAU

The Yucca Flat/Climax Mine CAU is in the latter part of the investigation stage of the closure process. The groundwater flow and contaminant transport model was completed in September 2013 (N-I 2013). A formal independent peer review was initiated in April 2014 and completed in December 2014. The peer review committee recommended moving forward into the model evaluation stage by initiating model evaluation studies that may include data collection and model refinements (N-I 2015).

11.1.2 Quality Assurance

The UGTA Quality Assurance Plan (QAP) (NNSA/NSO 2012) provides the overall quality assurance requirements and general quality practices that are applied to UGTA drilling, laboratory analyses, and modeling. The UGTA QAP complies with DOE Order DOE O 414.1D, “Quality Assurance”; *Guidance for Quality Assurance Project Plans for Modeling* (U.S. Environmental Protection Agency [EPA] 2002); and *Guidance on the Development, Evaluation, and Application of Environmental Models* (EPA 2009). UGTA work is conducted under the UGTA QAP in conjunction with other UGTA participants’ quality assurance programs. In 2014, quality assurance activities included conducting oversight assessments, identifying findings and completing corrective actions, and evaluating laboratory performance. These activities are described in an annual quality assurance report (NNSA/NFO 2015a). In addition, UGTA documents and models undergo thorough preemptive reviews throughout the investigation and model evaluation stages of the CAU closure process as well an independent formal peer review at the end of the investigation stage. Chapter 16 discusses the quality assurance and quality control procedures used for collecting and analyzing groundwater samples.

11.1.3 Other Activities and Studies

Compiling, evaluating, and updating various databases continued as an ongoing effort. A new UGTA water chemistry database was built in 2014, which combines data from two types of sources, commercial and noncommercial laboratories. The USGS continued their efforts in 2014 to establish a sample photo archive related to UGTA investigations and continued their water-level monitoring program. The photo archive, water levels, and other pertinent NNS information and data sets can be accessed through the USGS/U.S. Department of Energy Cooperative Studies in Nevada website at http://nevada.usgs.gov/doe_nv/. In addition, Navarro evaluated a new pumping technology for collecting samples from narrow diameter piezometers, which could not be sampled using previously available technologies (N-I 2014b). This technology will expand the number of wells and aquifers that UGTA can monitor.

11.1.4 UGTA Publications

All reports and publications that were completed in 2014 and published by June 2015 are listed in Table 11-1. Some of the published technical reports can be obtained from DOE’s Office of Scientific and Technical Information (OSTI) at <http://www.osti.gov/bridge>, and the OSTI identification number (ID) for those reports is provided.

Analysis of Trace Neptunium in the Vicinity of Underground Nuclear Tests at the Nevada National Security Site	Zhao et al. 2014

11.2 Industrial Sites

NNSA/NFO has identified 1,865 Industrial sites CASs on and off the NNSS for which they are responsible for characterization and closure under the FFACO. Closure strategies include removal of debris, excavation of soil, decontamination and decommissioning, and closure-in-place with subsequent monitoring. Radioactive materials removed from sites were either disposed as low-level waste (LLW) or mixed low-level waste (MLLW) at the Area 5 Radioactive Waste Management Site (RWMS) (see Section 10.1). Hazardous waste (HW) removed from the CASs was shipped to approved offsite treatment and disposal facilities or recycled. Beyond remediation, the Industrial Sites Activity ensures that long-term monitoring programs are in place to protect the safety of the public and the environment.

A total of 1,853 Industrial sites CASs have been closed and approved by the State. In 2014, four CASs were added to Industrial sites CAU 572. No Industrial sites CASs were closed, and no interim work related to their closure was conducted in 2014. Only 12 Industrial sites CASs from three CAUs remain to be closed. The three CAUs are CAU 114, Area 25 Engine Maintenance, Assembly, and Disassembly (EMAD) Facility; CAU 572, Test Cell C Ancillary Buildings and Structures; and CAU 575, Area 15 Miscellaneous sites. Their closure will occur prior to the end of the NNSS Environmental Restoration Activity, which is currently planned for 2030.

11.3 Soils

NNSA/NFO has identified 134 Soils CASs on and off the NNSS for which they are responsible for characterization and closure under the FFACO. Corrective actions range from removal of soil to closure-in-place with restricted access controls. Historical research and the preparation of summary reports have been completed for all 134 CASs. In 2014, 16 Soils CASs from three CAUs on the NNSS were closed (Table 11-2), and work was conducted towards closure at 39 CASs in 10 CAUs (Table 11-3).

Noteworthy progress was made in 2014 towards closure of Clean Slate II and III (CAUs 413 and 414, respectively) on the Tonopah Test Range (Table 11-3). In a joint effort with the U.S. Air Force and Sandia National Laboratories, NNSA/NFO completed a campaign to remove contaminated equipment and debris at these two historical nuclear testing locations after several months of intensive field work. Environmental cleanup crews removed contaminated drums, shipping containers, debris piles, and machinery. LLW was properly packaged for disposal on the NNSS at the Area 5 RWMS. This 2014 effort followed an initial surface cleanup campaign conducted in the late 1990s.

The total number of Soils CASs closed and approved by the State by the end of 2014 was 95. Closure of CASs on the TTR and NTTR require negotiation with the State of Nevada and the U.S. Department of Defense. The anticipated date for Soils closure is FY 2027; 39 Soils CASs remain to be formally closed.

Table 11-2. Soils Sites closed in 2014

CAU	CAU Description	Number of CASs	Corrective Actions	Wastes Generated ^(a)
105	Area 2 Yucca Flat Atmospheric Test Sites	5	Clean closure ^(b) , closure-in-place with use restrictions ^(c)	MLLW, LLW, Sanitary
366	Area 11 Plutonium Valley Dispersion Sites	6	Closure-in-place with use restrictions, no further action	LLW, Sanitary
571	Area 9 Yucca Flat Plutonium Dispersion Sites	5	Closure-in-place with use restrictions	LLW, Sanitary

(a) In addition to wastes, recyclable materials were recovered from all three CAUs.

(b) Clean closure is the removal of pollutants, contaminants, and waste at a CAS in accordance with Corrective Action Plans.

(c) Closure-in-place with use restrictions is the isolation of contamination with restricted access controls.

Table 11-3. Other Soils Sites where work was conducted in 2014

CAU	CAU Description	Number of CASs	Activity	Wastes Generated
411	Double Tracks Plutonium Dispersion (Nellis)	1	Preliminary investigation	None
412	Clean Slate I Plutonium Dispersion (TTR)	1	Preliminary investigation	None
413	Clean Slate II Plutonium Dispersion (TTR)	1	Preliminary investigation and waste disposition	LLW, Sanitary
414	Clean Slate II Plutonium Dispersion (TTR)	1	Preliminary investigation and waste disposition	LLW, Sanitary
415	Project 57 No. 1 Plutonium Dispersion (NTTR)	1	Preliminary investigation	LLW
541	Small Boy	2	Preliminary investigation	None
550	Smoky Contamination Area	19	Investigation of nature and extent of contamination and closure activities	MLLW, LLW, Sanitary
567	Miscellaneous Soil Sites	5	Investigation of nature and extent of contamination	None
568	Area 3 Plutonium Dispersion Sites	6	Investigation of nature and extent of contamination	None
573	Alpha Contaminated Sites	2	Preliminary investigation	None

11.3.1 Monitoring Activities at Soils CAUs

NNSA/NFO monitors airborne radiation and meteorological parameters on the TTR and NTTR to determine if there is wind transport of man-made radionuclides from the contaminated Operation Roller Coaster CAUs: Double Tracks Plutonium Dispersion (Nellis) (CAU 411), and the Clean Slate I, II, and III Plutonium Dispersion (TTR) CAUs (412, 413, and 414, respectively). In 2008, NNSA/NFO established air monitoring stations at Clean Slate III and the Range Operations Center. In 2011, a third air monitoring station was installed at Clean Slate I. The design of these stations is similar to that used in the Community Environmental Monitoring Program (CEMP) (see Chapter 7, Section 7.1). These monitoring efforts are not required under the FFACO. In 2014, no man-made radionuclides were detected in any of the air samples collected from these stations; only naturally occurring radionuclides were identified. Sandia National Laboratories reports this monitoring in the TTR annual environmental report, which is posted at <http://www.sandia.gov/news/publications/environmental/index.html>.

NNSA/NFO also monitors meteorological and surface runoff data from two Soils CAUs on the NNSS: Smoky Contamination Area (CAU 550) in Area 8 and the Area 11 Plutonium Valley Dispersion Sites (CAU 366). In 2011, one meteorological station and a flume to measure channelized runoff were installed at CAU 550, and two meteorological stations and an instrument station to collect surface water runoff and transported suspended and bedload sediments were installed at CAU 366. These stations are similar in design and function to those used in the CEMP with the exception of not including air filter monitoring or pressurized ion chambers. The equipment at both sites collect data to develop an understanding of meteorological conditions that contribute to contaminated soil transport. These monitoring efforts are not required under the FFACO but are conducted to aid in developing closure designs and post-closure monitoring requirements.

During FY 2014 (October 1, 2013–September 30, 2014), data from the CAU 550 meteorological station, the flume, and visual observations of sediment transport were summarized monthly and evaluated. Surface water flowed along the monitored channel during one or more precipitation events at CAU 550, and measurable transport of radionuclide-contaminated soil occurred during one of these events. All data collected in FY 2014 are reported in Miller et al. (2015a). In FY 2014, air monitoring data collected at CAU 366 identified wind speed conditions that resulted in increased dust transport and, thus, the potential re-suspension of contaminated soils. Also, one surface water runoff event occurred that was of sufficient volume to collect bedload transport samples for radiological analyses but was not of sufficient volume to collect suspended sediment samples. Man-made radionuclides were detectable in the bedload transport samples at levels typical of the sample location. The FY 2014 findings for CAU 366 are summarized in Miller et al. (2015b).

11.4 Post-Closure Monitoring and Inspections

All nine of the historical waste management units on the NNSS identified for closure under the Resource Conservation and Recovery Act (RCRA) (see Section 2.5) have been closed (Table 11-4). The NNSS RCRA Part B Permit prescribes post-closure monitoring requirements for six of these sites (Table 11-4). CAUs 110 and 111 require vadose zone monitoring (VZM) of the engineered covers over the craters/waste pits. The covers were designed to limit infiltration into the disposal units and are monitored using time-domain reflectometry soil water content sensors buried at various depths in the waste covers to provide water content profile data. The data are used to demonstrate whether the covers are performing as expected. The covers were vegetated with native vegetation and are monitored for vegetation success.

Table 11-4. Historical RCRA closure sites and their post-closure monitoring requirements

CAU	Remediation Site	Post-closure Requirements
90	Area 2 Bitcutter Containment	Semi-annual site inspection
91	Area 3 U-3fi Injection Well	Semi-annual site inspection
92	Area 6 Decon Pond Facility	Quarterly site inspection Inspection if precipitation >0.5 inches/24-hour period
93	Area 6 Steam Cleaning Effluent Ponds	None
94	Area 23 Building 650 Leachfield	None
109	Area 2 U-2bu Crater	None
110	Area 3 Waste Management Division (WMD) U-3ax/bl Crater	Quarterly site inspection VZM of the engineered cover caps Biennial subsidence survey Annual vegetation survey
111	Area 5 WMD Retired Mixed Waste Pits	Quarterly site inspection Inspection if precipitation >0.5 inches/24-hour period Annual subsidence survey Annual vegetation survey Quarterly TLD readings Tritium air analyses Gamma-emitting and isotopic radionuclide air analyses Annual measurements of radon flux Groundwater monitoring of Wells UE5 PW-1, -2, and -3 VZM of the engineered cover caps
112	Area 23 Hazardous Waste Trenches	Quarterly site inspection

In 2014, VZM results for CAUs 110 and 111 indicated that surface water is not migrating into buried wastes and that the covers are functioning as designed (NSTec 2015a). For CAU 111, external radiation measurements from thermoluminescent dosimeters (TLDs), air and groundwater sample analyses for radionuclides, and radon flux measurements indicate that the closure covers are performing within expectations and parameter assumptions of performance assessment models and there is no impact on the surrounding environment (NSTec 2015a; 2015b). One report for all RCRA closure sites monitored in FY 2014 was submitted to NDEP in January 2015 (NNSA/NFO 2015b).

Post-closure inspections are also required for many of the closed remediation sites managed under the FFAO that are not included in the RCRA Part B Permit (non-RCRA CASs). In 2014, NNSA/NFO conducted visual

inspections at 165 closed non-RCRA CASs managed under the FFAO. Several CASs that do not require inspections were inspected as a best management practice to ensure that the signs are intact. A 2014 annual inspection report for non-RCRA post-closure sites on the NNS was prepared and submitted to NDEP in May 2015 (NNSA/NFO 2015c). A 2014 annual inspection report for post-closure sites on the TTR was prepared and submitted to NDEP in March 2015 (NNSA/NFO 2015d).

11.5 Restoration Progress under the FFAO

In 2014, NNSA/NFO closed 16 CASs and completed all 2014 FFAO milestones. Figure 11-5 depicts the progress made since 1996 in the remediation of all historically contaminated sites managed under the FFAO. A total of 2,091 of the 3,025 CASs have been closed; they include 142 sites that have been closed by the DOE Office of Legacy Management, the Defense Threat Reduction Agency, or other owners. Of the remaining 934 CASs yet to be closed under the FFAO (929 of which are the responsibility of NNSA/NFO), 878 (94%) of them are UGTA CASs, which will be closed in place with monitoring in perpetuity. The public can view an interactive map that shows all CASs on the NNS, NTTR, and TTR at the following NNS Remediation Sites website: <http://nnsremediation.dri.edu/>. The website identifies all CASs that have been closed and those that are still open.

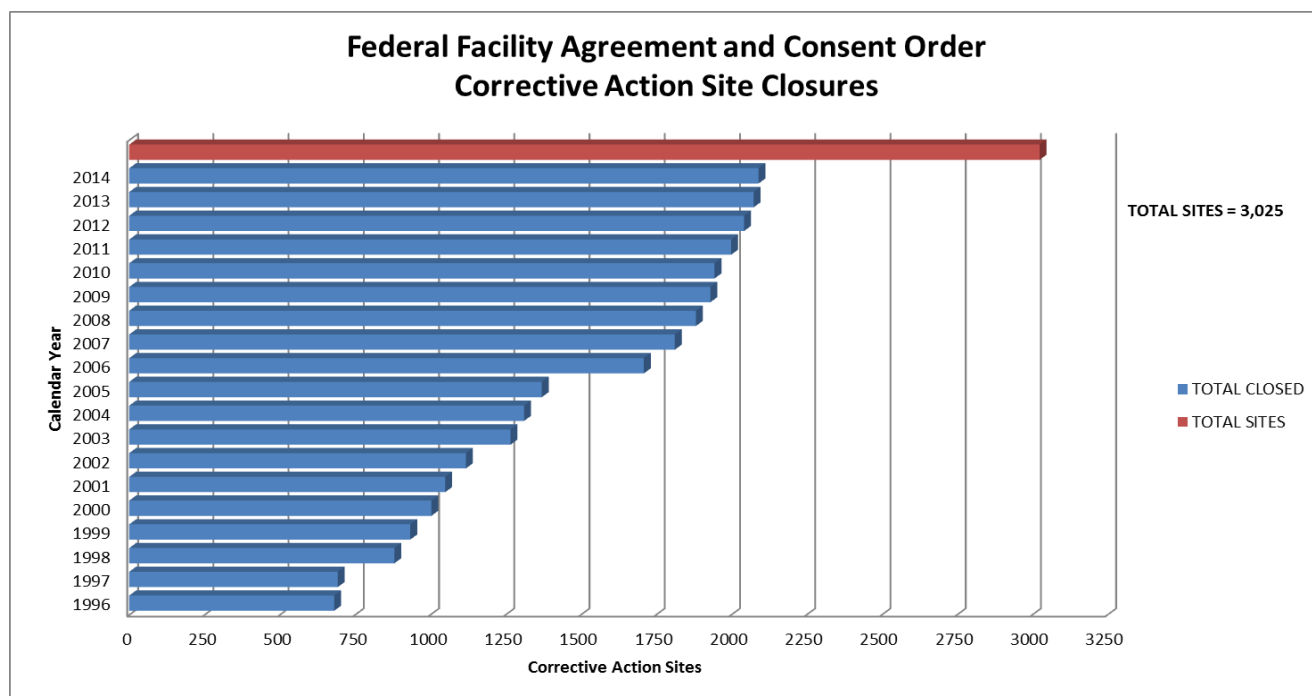

Figure 11-5. Annual cumulative totals of FFAO CAS closures

Chapter 12: Hazardous Materials Control and Management

Desiree M. Demers, Coby P. Moke, and Kevin E. Olsen

National Security Technologies, LLC

Hazardous materials used or stored on the Nevada National Security Site (NNSS) are controlled and managed through the use of a Hazardous Substance Inventory database. All contractors and subcontractors of the U.S. Department of Energy, National Nuclear Security Administration Nevada Field Office (NNSA/NFO) use this database if they use or store hazardous materials. They are required to comply with the operational and reporting requirements of the Toxic Substances Control Act (TSCA); the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA); the Emergency Planning and Community Right-to-Know Act (EPCRA); and the Nevada Chemical Catastrophe Act (see Section 2.6). Chemicals to be purchased are subject to a requisition compliance review process. Hazardous substance purchases are reviewed to ensure that toxic chemicals and products were not purchased when less hazardous substitutes were commercially available. Requirements and responsibilities for the use and management of hazardous/toxic chemicals are provided in company documents and are aimed at meeting the goals shown below. The reports and activities prepared or performed in 2014 to document compliance with hazardous materials regulations are presented below.

Hazardous Materials Control and Management Goals

Minimize the adverse effects of improper use, storage, or management of hazardous/toxic chemicals.
Ensure compliance with applicable federal and state environmental regulations related to hazardous materials.

12.1 TSCA Program

There are no known pieces of polychlorinated biphenyl (PCB)-containing electrical equipment (transformers, capacitors, or regulators) at the NNSS. However, sometimes during demolition activities, old hydraulic systems or contaminated soils are found to contain PCB liquids. The TSCA program consists mainly of properly characterizing, storing, and disposing of various PCB wastes generated through remediation activities and maintenance of fluorescent lights. The remediation waste is generated at corrective action sites during environmental restoration activities (see Chapter 11) and during maintenance activities and building decontamination and decommissioning activities. These activities can generate PCB-contaminated fluids and soil, along with bulk product waste containing PCBs.

Waste classified as bulk product waste that is generated on the NNSS can be disposed of on site in the Area 9 U10c Solid Waste Disposal Site with prior State of Nevada approval. PCB-containing light ballasts removed during normal maintenance can also go to this onsite landfill, but when remediation or upgrade activities generate several ballasts, these must be disposed of off site at an approved PCB disposal facility. Soil and other materials contaminated with PCBs must also be sent off site for disposal.

During 2014, two activities generated PCB regulated waste:

- Renovation activities generated nine drums of PCB light ballasts weighing 892 kg (1,960 lb), eight of which were shipped off site from the Hazardous Waste Storage Unit (HWSU) in Area 5 for disposal.
- Maintenance activities at the NNSS generated eleven drums of PCB light ballasts weighing 1,286 kg (2,825 lb), five of which were shipped off site from the HWSU for disposal.

Onsite PCB records continue to be maintained as required by the U.S. Environmental Protection Agency (EPA), and PCB management activities are documented herein annually. If any generated PCB wastes that are above threshold levels are released, they are also reported in the Toxic Release Inventory (TRI) Report (see Section 12.3). The EPA did not conduct any TSCA inspections at the NNSS in 2014.

The onsite disposal of radioactive waste received from offsite waste generator facilities that contain regulated quantities of PCBs is managed by Waste Management (see Section 10.1.1)

12.2 FIFRA Program

Several oversight functions are performed each year to ensure FIFRA compliance. They include the screening of all purchase requisitions for restricted-use pesticides/herbicides; the review of operating procedures for handling, storing, and applying pesticide/herbicide products; and monthly inspections of stored pesticides/herbicides. On the NNSS, pesticides and herbicides are applied under the direction of a State of Nevada–certified applicator. This service is provided by Solid Waste Operations (SWO). Pesticide applications in NNSS food service facilities are also conducted by SWO. Only one restricted-use chemical is used on the NNSS, which is an herbicide for vegetation control along the edges of paved roads. It is the same herbicide used by the State of Nevada along highway shoulders. SWO maintains the appropriate Commercial Category (Industrial) certification for applying this herbicide. All other pesticides/herbicides used are categorized as non-restricted-use (i.e., available for purchase and application by the general public). The entire restricted-use herbicide inventory was used in the first part of 2014. There are no plans to order any more of this herbicide. Monthly inspections in 2014 found that all pesticides/herbicides were stored in accordance with their labeling. The State of Nevada did not conduct an inspection of pesticide storage facilities in 2014.

12.3 EPCRA Program

EPCRA requires that federal, state, and local emergency planning authorities be provided information regarding the presence and storage of hazardous substances and extremely hazardous substances (EHSs) and their planned and unplanned environmental releases, including provisions and plans for responding to emergency situations involving hazardous materials. NNSA/NFO prepares and submits reports in compliance with EPCRA pursuant to Sections 302, 304, 311, 312, and 313 of the Superfund Amendments and Reauthorization Act, Title III (Table 12-1).

Table 12-1. Reporting criteria of the Emergency Planning and Community Right-to-Know Act

Section	CFR Section	Reporting Criteria	Agencies Receiving Report
302	40 CFR 355: Emergency Planning Notifications	The presence of an EHS in a quantity equal to or greater than the threshold planning quantity at any one time.	SERC ^(a) , LEPC ^(b)
		Change occurring at a facility that is relevant to emergency planning.	LEPC
304	40 CFR 355: Emergency Release Notifications	Release of an EHS or a CERCLA hazardous substance ^(c) in a quantity equal to or greater than the reportable quantity.	SERC, LEPC
311	40 CFR 370: Material Safety Data Sheet Reporting	The presence at any one time at a facility of an OSHA hazardous chemical ^(d) in a quantity equal to or greater than 4,500 kg (10,000 lb) or an EHS in a quantity equal to or greater than the threshold planning quantity or 230 kg (500 lb), whichever is less.	SERC, LEPC, Local Fire Departments
312	40 CFR 370: Tier Two Report	Same as Section 311 reporting criteria above.	SERC, LEPC, Local Fire Departments
313	40 CFR 372: Toxic Release Inventory Report	Manufacture, process, or otherwise use at a facility, any listed TRI chemical in excess of its threshold amount during the course of a calendar year. Thresholds are 11,300 kg (25,000 lb) for manufactured or processed or 4,500 kg (10,000 lb) for otherwise used, except for persistent, bio-accumulative, toxic chemicals, which have thresholds of 45 kg (100 lb) or less.	EPA, SERC

(a) SERC = State Emergency Response Commission

(b) LEPC = Local Emergency Planning Commission

(c) Hazardous substance as defined in the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), 40 CFR 302.4

(d) Hazardous chemical as defined in the Occupational Safety and Health Act, 29 CFR 1910.1200

In response to the EPCRA requirements, all chemicals that are purchased are entered into the Hazardous Substance Inventory database and assigned specific hazard classifications (e.g., corrosive liquid, flammable, toxic). Annually, this database is updated to show the maximum amounts of chemicals that were present in each building at the NNSS, North Las Vegas Facility (NLVF) (see Section A.1.5), and the Remote Sensing Laboratory–Nellis (RSL–Nellis) (see Section A.2.4). Inventory data are used to complete the Nevada Combined Agency (NCA) Report. The NCA Report provides information to the State of Nevada, community, and local emergency planning commissions on the maximum amount of any chemical, based on its hazard classification, present at any given time during the preceding year. The State Fire Marshal then issues permits to store hazardous chemicals on the NNSS as well as at RSL–Nellis and NLVF. The 2014 chemical inventory for NNSS facilities was updated and submitted to the State of Nevada in the NCA Report on February 13, 2015. The NCA Report satisfies EPCRA Section 302, 311, and 312 reporting requirements. No EPCRA Section 304 reporting was required in 2014 because no accidental or unplanned release of an EHS occurred at the NNSS, NLVF, or RSL–Nellis.

The Hazardous Substance Inventory database is also a data source for the TRI Report. This database provides quantities of TRI chemicals that were used at the NNSS as part of normal business operations throughout the previous year. Toxic chemicals included in the TRI Report are typically released to the environment through air emissions, landfill disposal, and recycling. Reuse of a material, however, does not constitute a release to the environment. TRI toxic chemicals that are recovered during NNSS remediation activities or become “excess” to operational needs (e.g., lead bricks, lead shielding) are sent off site for recycling, reuse, or proper disposal. Mixed wastes generated at other DOE facilities and sent to the NNSS for disposal may contain TRI toxic chemicals that must be reported in the TRI Report.

In 2014, lead, mercury, and PCBs that were released as a result of NNSS activities, were determined to be reportable under EPCRA Section 313. No release activities at NLVF or RSL–Nellis exceeded reportable thresholds in 2014. Table 12-2 lists the 2014 NNSS release quantities by type of activity for the three reportable TRI toxic chemicals. In June 2015, NNSA/NFO submitted the TRI Report for calendar year 2014 to the EPA and the State Emergency Response Commission.

Table 12-2. Summary of 2014 reported releases under EPCRA Section 313

Reported Release	Quantity ^(a) (pounds [lb])		
	Lead	Mercury	PCB
Air Emissions ^(b)	2.5	0	0
Onsite Disposal ^(c)	34,053	410.14	29.69
Onsite Release ^(d)	4,094	0	0
Offsite Recycling ^(e)	43,238.10	0.062	0
Offsite Disposal ^(f)	84.18	0.002	1.717
Cleanup Activities or One-time Events	0	0	0
Totals	81,471.78	410.20	31.40
EPCRA Reporting Thresholds	100	10	10

(a) The weight of the chemical released, not the weight of the waste material containing the toxic chemical.

(b) Airborne releases of lead during firing at the Mercury Firing Range.

(c) Mixed low level waste or hazardous waste containing lead, mercury, or PCB that was disposed in Cell 18 at the Area 5 Radioactive Waste Management Site (RWMS) (see Section 10.1.1).

(d) Spent ammunition left on the ground during firing at the Mercury Firing Range. When the firing range is closed, ammunition will be collected for recycling.

(e) Lead was from three waste streams: 42,880 lb of lead-acid batteries, 160 lb of scrap metal, and 198 lb of miscellaneous lead items. Mercury was from fluorescent lamps.

(f) Lead was from lead paint removal and other routinely generated waste. Mercury was from circuit board debris. PCBs were from light ballasts, contaminated debris, and PCB oil.

In February 2014, NNSA/NFO submitted revised TRI Reports for calendar years 2011 and 2012 to the EPA and the State Emergency Response Commission. The revisions contained the quantities of PCBs released during those years which exceeded reportable thresholds under EPCRA Section 313, which had been incorrectly reported. The originally reported and revised release quantities were documented in Chapter 12, Section 12.3, Table 12-3 of NSTec (2014).

No EPCRA inspections were performed by outside regulators in 2014.

12.3.1 Hazardous Substance Inventory Updating

In 2014, plans were made to revamp the Hazardous Substance Inventory database to allow for real-time tracking of chemicals stored and used throughout the complex. The annual inventory of chemicals was completed at the end of 2014, and the inventory data will begin to be transferred in 2015 to a separate module of an enterprise asset management software system called Maximo. The new program, once completed, is anticipated to allow the tracking of chemicals from the moment they arrive at NNSS, NLVF, or RSL-Nellis to when they are disposed and to provide an accurate account of chemicals on site at any point in time. It will provide chemical owners with additional information including purchase dates, Safety Data Sheets, storage locations, and expiration dates. It is expected that the program will also aid in reducing the quantities of chemicals stored on site since excess chemicals in the inventory can be flagged to facilitate their transfer and use before additional quantities are purchased. Progress towards updating the Hazardous Substance Inventory will be reported in the 2015 NNSS Environmental Report.

12.4 Nevada Chemical Catastrophe Prevention Act

The Nonproliferation Test and Evaluation Complex in Area 5 of the NNSS is registered as a Nevada Chemical Accident Prevention Program (CAPP) facility. NNSA/NFO is required to submit an annual CAPP Registration report to the State of Nevada whether or not a threshold was exceeded. The CAPP Registration report for operations from June 2013 through May 2014 was submitted to NDEP on June 19, 2014. No highly hazardous substances were stored in quantities that exceeded reporting thresholds.

Chapter 13: Groundwater Protection

Coby P. Moke and Dawn M. Starrett

National Security Technologies, LLC

Robert P. Graves

U.S. Geological Survey

This chapter presents other programs and activities of the U.S. Department of Energy, National Nuclear Security Administration Nevada Field Office (NNSA/NFO) that are related to the protection of groundwater that have not been discussed in previous chapters of this report (Chapter 5, Water Monitoring; Chapter 7, Section 7.2, Offsite Surface and Groundwater Monitoring; Chapter 10, Section 10.1.7, Groundwater Monitoring, and Section 10.1.8, Vadose Zone Monitoring; and Chapter 11, Section 11.1, UGTA Sites).

It is the policy of NNSA/NFO to prevent pollutants, both from past and current Nevada National Security Site (NNSS) activities, from impacting the local groundwater. Under current NNSA/NFO missions, groundwater-related activities focus on preventing groundwater contamination, protecting the public and environment from past contamination, and protecting groundwater quality and availability for current and future NNSS missions. NNSA/NFO acknowledges that the greatest potential for environmental impact at the NNSS is the resumption of underground testing of nuclear devices and their components. If such testing were resumed in the future, the groundwater protection policy of NNSA/NFO would be to minimize, rather than eliminate, the impacts of testing.

Groundwater Protection Program Goals

Prevent the degradation of water quality due to NNSA/NFO activities that would be harmful to the public, the environment, or biota.

Conduct research and monitoring to prevent public exposure to drinking water contaminated by past nuclear testing activities.

Protect water availability for current and future NNSS activities.

13.1 Wellhead Protection

NNSA/NFO seeks to protect groundwater from the infiltration or introduction of contaminants at the wellhead through a variety of procedures and programs. Source Water Protection areas on the NNSS have been identified by the State of Nevada for NNSS water supply wells, and inventories and assessments of potential contaminant sources within these areas have been performed. Wellheads are routinely surveyed to identify potential new contaminant sources. Wellheads are protected from public access by locked well caps and by the prohibition of public access onto NNSS land enforced by site security. NNSA/NFO wells that are sampled are protected through adherence to proper groundwater sampling procedures developed by each NNSS contractor or tenant organization. These procedures must be identified and implemented as a condition of well access authorization under an NNSA/NFO permit called a Real Estate Operations Permit.

13.2 Spill Prevention and Management

Procedures for the prevention, control, cleanup, and reporting of spills of hazardous and toxic materials, or any other regulated material, into the environment are established for all NNSA/NFO-managed facilities. Spills include releases from underground tanks, aboveground tanks, containers, equipment, or vehicles. All users of the NNSS are instructed to prevent, control, and report spills. NNSA/NFO ensures that spills are reported to proper federal, state, and county regulatory agencies, if required, and are properly mitigated by removing and disposing the contaminated media. All federal and state regulations concerning spills under the Clean Water Act, the Resource Conservation and Recovery Act, Superfund Amendments and Reauthorization Act, Emergency Planning and Community Right-to-Know Act, and state-specific requirements are followed.

Spill Prevention, Control, and Countermeasure (SPCC) plans are in place for the North Las Vegas Facility (NLVF) and the Remote Sensing Laboratory–Nellis (RSL–Nellis) to prevent discharges of petroleum products and non-petroleum oils and greases into the Las Vegas Wash. The plans were prepared in accordance with the Clean Water Act, and cover petroleum-storage areas and petroleum-containing equipment, including transformers and machine tools. The NNSS does not have an SPCC because the NNSS oil storage areas do not have the potential to impact any protected waterways. Established procedures for users of the NNSS as well as the NLVF and RSL–Nellis ensure that surface spills or subsurface releases of contaminants do not infiltrate groundwater or flow into surface waters. In 2014, there were no reportable spills.

13.3 Water Level and Usage Monitoring by the USGS

The U.S. Geological Survey (USGS) Nevada Water Science Center collects, compiles, stores, and reports hydrologic data used in determining the local and regional hydrogeologic conditions in and around the NNSS. Hydrologic data are collected quarterly or semi-annually from wells on and off the NNSS. The USGS also maintains and develops the Death Valley Regional Groundwater Flow System Model (Belcher and Sweetkind 2010) and manages the NNSS well hydrologic and geologic information database.

During 2014, the USGS monitored water levels in 220 wells, which included 107 on the NNSS and 113 off the NNSS. A map showing the location of monitored wells and all water-level data are posted on the USGS/ U.S. Department of Energy (DOE) Cooperative Studies in Nevada web page at http://nevada.usgs.gov/doe_nv/.

Groundwater-use data are collected from water supply wells on the NNSS using flow meters, and are reported monthly. The principal NNSS water supply wells monitored during 2014 included J-12 WW, J-14 WW, UE-16d WW, WW #4, WW #4A, WW 5B, and WW 8 (see Chapter 5, Figure 5-2). The USGS compiles the annual water-use data and reports annual withdrawals in millions of gallons. Discharge data from these wells for 2014 have been compiled, processed, and entered onto the USGS/DOE Cooperative Studies in Nevada website at http://nevada.usgs.gov/doe_nv/wateruse/wu_map.cfm. Discharge from these wells during 2014 was approximately 118 million gallons (Figure 13-1).

Figure 13-1. Annual withdrawals from the NNSS, 1951 to 2014

13.4 Groundwater Conservation

All water used at the NNSS is groundwater. NNSA/NFO takes actions to conserve groundwater by addressing the water efficiency and water management goals presented in DOE's Strategic Sustainability Performance Plan (DOE 2014) and in the NNSA/NFO Site Sustainability Plan (National Security Technologies, LLC [NSTec], 2014). These goals include reducing both potable and non-potable water use (see Chapter 3, Table 3-1, Goal 4). As shown in Figure 13-1, current water usage has dropped to levels that have not been seen since the early 1960s due to changes in site operations and to recent conservation actions.

A Water Management Plan for the NNSS, developed in 2011 (The Delphi Groupe, Inc. [Delphi] 2011), includes a water metering plan, a comprehensive plan to reduce groundwater usage and losses on site, a water system configuration improvement plan, and water efficiency practices implemented on the NNSS. In 2014, WaterSense labeled products continued to be purchased and installed, as identified in the Water Management Plan, to replace standard faucets and toilets on an as-needed basis. Rebates from the Southern Nevada Water Authority for the installation of water-saving devices continued to be sought and, when obtained, will be used to fund additional water-saving initiatives.

In 2014, NNSA/NFO exceeded the water use efficiency and management goals established by DOE (Chapter 3, Table 3-2, Goal 4). Because of this, large and costly water saving projects such as the replacement of aging waterlines in Area 23 and throughout the NNSS, which is an identified conservation action under the Water Management Plan (Delphi 2011), will be pursued only when additional funding is acquired. Current and near future water saving projects will be limited to routine maintenance.

Chapter 14: Historic Preservation and Cultural Resources Management

Colleen M. Beck, Barbara A. Holz, and Richard Arnold

Desert Research Institute

The historic landscape of the Nevada National Security Site (NNSS) contains archaeological sites, buildings, structures, and places of importance to American Indians and others. These are referred to as “cultural resources.” U.S. Department of Energy (DOE) Order DOE O 436.1, “Departmental Sustainability,” requires the development and maintenance of policies and directives for the conservation and preservation of cultural resources. On the NNSS, cultural resources are monitored, and site activities and projects comply with applicable federal and state regulations related to their protection (see Section 2.8). The Cultural Resources Management (CRM) program at the NNSS has been established by the U.S. Department of Energy, National Nuclear Security Administration Nevada Field Office (NNSA/NFO) and is implemented by the Desert Research Institute (DRI) to aid in the conservation and preservation of cultural resources that may be impacted by NNSA/NFO activities. The CRM program is designed to meet the specific goals shown below.

<i>Cultural Resources Management Program Goals</i>
Ensure compliance with all regulations pertaining to cultural resources on the NNSS (see Section 2.8).
Inventory and manage cultural resources on the NNSS.
Provide information that can be used to evaluate the potential impacts of proposed projects and programs to cultural resources on the NNSS and mitigate adverse effects.
Curate archaeological collections in accordance with Title 36 Code of Federal Regulations (CFR) Part 79, “Curation of Federally-Owned and Administered Archeological Collections.”
Conduct American Indian consultation related to places and items of importance to the Consolidated Group of Tribes and Organizations.

In order to achieve the program goals and meet federal and state requirements, the CRM program is multifaceted and contains the following major components: (1) archival research, inventories, and historical evaluations; (2) curation of archaeological collections; and (3) the American Indian Consultation Program. The guidance for the CRM program work is provided in the *Cultural Resources Management Plan for the Nevada Test Site* (Drollinger and Beck 2010). Historic preservation personnel and archaeologists of DRI who meet the qualification standards set by the Secretary of the Interior conduct the work, and the archaeological efforts are permitted under the Archaeological Resources Protection Act (ARPA).

A brief description of the CRM program components and their 2014 accomplishments is provided in this chapter. The methods used to conduct inventories and historical evaluations in support of NNSS operations were summarized in the *Nevada Test Site Environmental Report 2003* (Bechtel Nevada 2004). The reader is directed to the *Nevada National Security Site Environmental Report 2014 Attachment A: Site Description*. It is a separate file on the compact disc of this report and is also accessible on the NNSA/NFO web page <http://www.nv.energy.gov/library/publications/aser.aspx>. Attachment A summarizes the known human occupation and use of the NNSS from the Paleo-Indian Period, about 12,000 years ago, until the mining and ranching period of the 20th century, just before NNSS lands were withdrawn for federal use.

14.1 Cultural Resources Inventories and Historical Evaluations

Cultural resources inventories are field surveys that are conducted at the NNSA to meet the requirements of the National Historic Preservation Act (NHPA) and the ARPA. The inventories are completed prior to proposed projects that may disturb or otherwise alter the environment. Historical evaluations are completed to evaluate historic buildings and structures for eligibility to the National Register of Historic Places (NRHP). The following types of information collected during inventories and historical evaluations, or produced based on them, are maintained in databases:

- Number of cultural resources inventories conducted
- Location of each inventory
- Number of acres surveyed at each project location
- Types of cultural resources identified at each project location
- Number of cultural resources determined eligible to the NRHP
- Eligible properties avoided by project activities
- Cultural resources requiring mitigation to address an adverse effect
- Occurrences of damage to archaeological sites
- Final report on results

In 2014, DRI conducted archival research for 39 proposed NNSA/NFO projects that had the potential to impact cultural resources on the NNSA. The archival research results led archeologists to conduct nine field inventories, and the inventories resulted in the identification of 18 historic sites and one multicomponent site (i.e., a site containing evidence/artifacts of both historic and prehistoric occupations). NRHP determinations are pending. A total of 226 hectares (556 acres) were examined during the inventories.

In 2014, one historic resource, a wooden structure associated with nuclear testing, was assessed for damage. The wooden structure was initially recorded in 2004 and in recent years noticeable changes from weathering have been apparent. By 2010, one wall collapsed inward and by late 2013, the other three walls had collapsed. This damage occurred during heavy wind gusts, particularly from the south (Drollinger 2013).

14.2 Evaluations of Historic Structures

In 2014, no new evaluations of historic structures were undertaken. One historical evaluation was completed, the U15 Complex, and it was determined eligible to the NRHP. The U15 Complex, in Area 15 of the NNSA, was in operation from 1959 to 1967 for the Hard Hat, Tiny Tot, and Pile Driver underground nuclear tests. The objective of these tests was to monitor the response of ground shock and various structure types to a nuclear explosion in order to design and construct underground facilities, such as command centers, that would be impervious to a direct nuclear attack (Drollinger et al. 2014). Subsequent to these tests, the complex was used for underground nuclear fuel storage experiments by the Lawrence Livermore National Laboratory for the DOE from 1978 to 1985. No major projects have been conducted at the site since then.

Work continued in 2014 on two historical evaluations, the Smoky atmospheric test and the Shasta atmospheric test. The Smoky atmospheric test was detonated in August 1957 on top of a 231.4 m (700 ft) 200-ton tower (T-2c) in Area 8 of the NNSA. Smoky was a weapons related test of the Plumbbob series and part of the Department of Defense Exercises Desert Rock VII and VIII. The Smoky test location is the best preserved post-shot atmospheric nuclear tower test at the NNSA and possibly in the world.

Figure 14-1. Structural frame above the main shaft to the underground U15 Complex.

The Shasta atmospheric nuclear test location, including its outlying instrument stations, are in Areas 2, 4, and 8. The Shasta nuclear device was detonated in August 1957 from the top of a 152.4-meter (500-foot), 200-ton steel tower named T2a in Area 2. The test was one of the mid-series tests of Operation Plumbbob. The primary objectives of the test were to evaluate newly designed devices, to evaluate the nuclear yield and blast of the Shasta device, and to investigate thermal and nuclear radiation phenomena. Cultural materials within the site area are features, artifacts, and structures related to the test (King 2012).

14.3 General Reconnaissance

Three field activities, two letter reports, and one preliminary assessment were conducted in 2014. One of the field activities was a site visit to the MX Complex in Area 25 to photograph and record features within a portion of the complex. The second field visit involved accompanying construction personnel to Area 4 to look at proposed locations for pits at the Big Explosives Experimental Facility. The third visit was to view the locations of proposed pads, a borrow pit, and an access road in Area 20. One of the letter reports addressed the historical significance of the Smoky atmospheric nuclear test location in Area 8 (Beck 2014). The second letter report summarized information on the Coulomb-C atmospheric nuclear test location in Area 3 (King 2014a). The one preliminary assessment was for Corrective Action Unit (CAU) 573, which comprises two corrective action sites (CASs). CAS 05-23-2 is associated with the Gadgets, Mechanics, and Explosives (GMX) experimental area, and CAS 05-45-01 focuses on a contaminated area surrounding the ground zero for the Hamilton atmospheric nuclear test (King 2014b).

Figure 14-2. Fast Photo Bunker for the Shasta test housed an ultra-high speed camera that recorded images of the nuclear detonation in microseconds.

14.4 Cultural Resources Reports

The report for the completed historical evaluation for the U15 Complex was finalized in 2014 (Drollinger et al. 2014). NNSA/NFO submitted the historical evaluation to the Nevada State Historic Preservation Office for review and received their concurrence that this location is eligible to the NRHP. The data on NNSA archaeological activities conducted by DRI for the NNSA/NFO in 2014 were provided to DOE Headquarters in the Federal Archeology Questionnaire for transmittal to the Secretary of the Interior and, ultimately, to the U.S. Congress as part of the Secretary of the Interior's Annual Archeology Report to Congress.

14.5 Curation

The NHPA requires that archaeological collections and associated records be maintained at professional standards; the specific requirements are delineated in 36 CFR 79. The NNSA Archaeological Collection currently contains over 400,000 artifacts and is curated in accordance with 36 CFR 79. Curation requirements for the NNSA Archaeological Collection include:

- Maintain a catalog of the items in the NNSA collection.
- Package the NNSA collection in materials that meet archival standards (e.g., acid-free boxes).
- Store the NNSA collection and records in a facility that is secure and has environmental controls.
- Establish and follow curation procedures for the NNSA collection and facility.
- Comply with the Native American Graves Protection and Repatriation Act (NAGPRA).

In the 1990s, the U.S. Department of Energy, Nevada Operations Office completed the required inventory and summary of NNSS cultural materials accessioned into the NNSS Archaeological Collection, and distributed the inventory list and summary to the tribes affiliated with the NNSS and adjacent lands. Consultations followed, and all artifacts the tribes requested were repatriated to them. This process was completed in 2002; it will be repeated for new additions to the collection in the future.

In 2014, the artifact catalog and accession records databases were maintained and updated as needed. Improvements were also made to the artifact collections and their associated records. The historic artifact collection was reorganized and relocated within the curation facility. The last boxes of prehistoric artifacts received from the University of Nevada, Las Vegas and boxes of historic nuclear testing related materials were accessioned, cataloged and then placed in the permanent collection. (Falvey and Menocal 2014). Also, representative prehistoric and historic artifacts were identified for use as display items during future tours of the collection facility (Falvey and Menocal 2014).

All artifacts in the collection are stored in current archival-quality materials, and almost 40 years of archaeological survey reports, technical reports, and site records are linked to a Geographical Information System. Although the work schedule in the curation facility is variable, the state of the collection is monitored weekly to ensure that the materials remain in good condition.

14.6 American Indian Consultation Program

NNSA/NFO has maintained an active American Indian Consultation Program (AICP) since the late 1980s. Its function is to conduct consultations between NNSA/NFO and 16 NNSS-culturally affiliated American Indian tribes collectively organized into the Consolidated Group of Tribes and Organizations (CGTO). The CGTO represents Southern Paiute, Western Shoshone, and Owens Valley Paiute-Shoshone. The 16 groups are listed in previous NNSS environmental reports (e.g., National Security Technologies, LLC, 2008). A history and overview of this program is contained in *American Indians and the Nevada Test Site, A Model of Research and Consultation* (Stoffle et al. 2001). The goals of the program are to:

- Provide a government-to-government forum for the CGTO to interface directly with NNSA/NFO management on topics of interest.
- Provide the CGTO with opportunities to actively participate and help guide decisions that involve culturally significant places, resources, and locations on the NNSS.
- Involve the CGTO in the curation, display, and protection of American Indian artifacts from the NNSS.
- Enable the CGTO and its constituency to practice and participate in religious and traditional activities within the boundaries of the NNSS.
- Provide opportunities for CGTO subgroups to participate in the review and evaluation of program documents on an interim basis between regularly scheduled meetings.
- Include the CGTO in the development of tribal text in the agency's National Environmental Policy Act documents.

Throughout 2014, NNSA/NFO interacted with the CGTO spokesperson and received regular updates relating to tribal activities and interactions. The spokesperson serves as a designated liaison to the Nevada Site Specific Advisory Board (NSSAB), attending regularly scheduled meetings and providing insight to tribal perspectives. Liaison involvement provides useful information for the NSSAB in their deliberations on recommendations to NNSS/NFO.

Ongoing updates about the CGTO and NNSS activities are provided through a series of DOE-sponsored groups, meetings, and activities. One primary example includes the State Tribal Government Working Group (STGWG) sponsored by DOE Environmental Management. STGWG comprises representatives from various state governments and 10 other tribes from New Mexico, Idaho, Washington, Oregon, and New York that are involved in DOE activities. STGWG meetings were held in Santa Fe, New Mexico on June 2–5 and again in New Orleans, Louisiana on November 12–14, 2014. STGWG meetings are an important forum for sharing information of

mutual interest and for engaging in discussions with DOE leadership, as were accomplished between the CGTO spokesperson and the Acting Assistant Secretary for the DOE Office of Environmental Management during the 2014 New Orleans STGWG meeting. Discussion topics typically focus on environmental management activities and methods for enhancing communications between the tribes and DOE.

In 2014, NNSA/NFO began plans to host an AICP tribal update meeting, and developed informational correspondence to be distributed to participating tribes concerning the meeting tentatively scheduled for July 2015. AICP meetings remain a priority and are determined beneficial in fostering tribal interactions with NNSA/NFO and in providing opportunities to discuss environmental activities on the NNSS.

On December 11–12, 2014, NNSA/NFO Assistant Director for Environmental Management, along with the NNSA/NFO AICP Manager and CGTO spokesperson, attended the DOE Tribal Summit and Dialogue in Phoenix, Arizona hosted by the DOE Secretary. Throughout this event, DOE/NFO representatives and the CGTO spokesperson participated in various working groups and shared insight about tribal involvement with the NNSS.

In 2014, NNSA/NFO did not receive any requests from culturally affiliated tribes to access the NNSS for ceremonial or traditional use. CGTO interests continue to focus on expanding tribal involvement in adapting traditional management activities and conducting further ethnographic studies to document traditional ecological knowledge of NNSS land use and cultural resource protection and preservation.

In the 1990s, NNSA/NFO initiated NAGPRA and completed consultations with NNSS culturally affiliated tribes. NNSA/NFO remains committed to maintaining compliance with curation standards and ensuring that positive relations continue to exist between NNSA/NFO and the tribes (Arnold, R. 2014).

Chapter 15: Ecological Monitoring

Derek B. Hall, W. Kent Ostler, Paul D. Greger, and David C. Anderson

National Security Technologies, LLC

The Ecological Monitoring and Compliance (EMAC) Program provides ecological monitoring and biological compliance support for activities and programs conducted at the Nevada National Security Site (NNSS). The major sub-programs and tasks within EMAC include (1) the Desert Tortoise Compliance Program, (2) biological surveys at proposed project/activity sites, (3) monitoring important species and habitats, (4) the Habitat Restoration Program, and (5) wildland fire hazard assessment. Brief descriptions of these sub-programs and their 2014 accomplishments are provided in this chapter. Detailed information may be found in the most recent annual EMAC report (Hall et al. 2015). EMAC annual reports are available at <http://www.nv.energy.gov/library/publications/emac.aspx>. The reader is also directed to *Attachment A: Site Description*, a separate file on the compact disc of this report, where the ecology of the NNSS is described.

Ecological Monitoring and Compliance Program Goals

Ensure compliance with all state and federal regulations and stakeholder commitments pertaining to NNSS flora, fauna, wetlands, and sensitive vegetation and wildlife habitats (see Section 2.9).

Delineate NNSS ecosystems.

Provide ecological information that can be used to evaluate the potential impacts of proposed projects and programs on NNSS ecosystems and important plant and animal species.

15.1 Desert Tortoise Compliance Program

The desert tortoise is federally protected as a threatened species under the Endangered Species Act, and it inhabits the southern one-third of the NNSS (Figure 15-1). Activities conducted in desert tortoise habitat on the NNSS must comply with the terms and conditions of a Biological Opinion (Opinion) issued to the U.S. Department of Energy, National Nuclear Security Administration Nevada Field Office (NNSA/NFO) by the U.S. Fish and Wildlife Service (FWS) (FWS 2009). The Opinion is effectively a permit to conduct activities in desert tortoise habitat in a specific manner. It authorizes the incidental “take” (accidental killing, injury, harassment, etc.) of tortoises that may occur during the activities, which, without the Opinion, would be illegal and subject to civil or criminal penalties.

The Opinion states that proposed NNSS activities are not likely to jeopardize the continued existence of the Mojave population of the species and that no critical habitat would be destroyed or adversely modified. It sets compliance limits for the acres of tortoise habitat that can be disturbed, the number of accidentally injured and killed tortoises, and the number of captured, displaced, or relocated tortoises (Table 15-1). It also establishes mitigation requirements for habitat loss. The Desert Tortoise Compliance Program was developed to implement the Opinion’s terms and conditions, document compliance actions taken, and assist NNSA/NFO in FWS consultations.

15.1.1 Surveys and Compliance Documentation

In 2014, biologists conducted surveys for 15 projects that were within the distribution range of the desert tortoise on or near the NNSS. At the project sites, no desert tortoises were accidentally injured or killed, nor were any found, captured, or displaced from the project sites. A total of 5.14 acres of desert tortoise habitat were disturbed in 2014, and no compliance limits of the Opinion were exceeded (Table 15-1). No desert tortoises were killed by vehicles on paved roads, and 13 were moved out of harm’s way off of roads.

Mitigation fees to compensate for the disturbance of the 5.14 acres were either paid and deposited into a Desert Tortoise Public Lands Conservation Fund or credited against the costs accrued by NNSA/NFO to conduct FWS-approved desert tortoise studies on the NNSS. The accrued costs are considered mitigation fees “earned” by the NNSA/NFO, which preclude payment of fees into the conservation fund by NNSA/NFO funded projects.

Figure 15-1. Desert tortoise distribution and abundance on the NNSS

Two desert tortoises that had been moved off of roads and an additional four desert tortoises were fitted with radio transmitters for an FWS-approved study (see Section 15.1.2). In January 2015, NNSA/NFO submitted a report to the FWS Southern Nevada Field Office that summarizes tortoise compliance activities conducted on the NNSS from January 1 through December 31, 2014.

Table 15-1. Annual totals (2014), cumulative totals (2009–2014), and compliance limits for take of acres and tortoises

Program/Activity	Acres Impacted			Tortoises Killed or Injured			Other Incidental Take ^(a)		
	Annual Total	Cumulative Total	Permit Limit	Annual Total	Cumulative Total	Permit Limit	Annual Total	Cumulative Total	Permit Limit
Defense	0	5.61	500	0	0	1	0	0	10
Waste Management	0	0	100	0	0	1	0	0	2
Environmental Restoration	0	0	10	0	0	1	0	0	2
Nondefense Research and Development	0	0	1,500	0	0	2	0	0	35
Work for Others	4.96	32.49	500	0	0	1	0	0	10
Infrastructure Development	0.18	8.43	100	0	0	1	0	0	10
Vehicle Traffic on Roads	-	-	-	0	7	15 ^(b)	17	76	125
Totals	5.14	46.53	2,710	0	7	22	17	76	194

(a) The number of desert tortoises that a qualified biologist can take by capture, displacement, relocation, or disruption of behavior if desert tortoises are found in harm's way within a project area or on a heavily trafficked road.

(b) No more than 4 desert tortoises killed during any calendar year and 15 during the term of the Opinion (2009–2019).

15.1.2 Desert Tortoise Conservation Projects

Three desert tortoise projects on the NNSS have been approved by the FWS and are being conducted solely or in part by NNSS biologists. They include (1) a tortoise movements study of up to 30 tortoises found along paved NNSS roads, (2) a study of the fate of 60 juvenile tortoises translocated in 2012 from captivity at the Desert Tortoise Conservation Center (DTCC) located near Las Vegas, Nevada, to undisturbed tortoise habitat in Area 22 of the NNSS by staff and volunteers from the San Diego Zoo Institute for Conservation Research (ICR), and (3) a collaborative behavioral/health study of up to 20 translocated tortoises within each of three existing fenced enclosures in Rock Valley (Area 25) led by the U.S. Geological Survey (USGS) in collaboration with the FWS, the ICR, and Pennsylvania State University.

NNSS biologists use radiotelemetry to document the location and condition of tortoises included in these three studies. In November 2013, the FWS approved NNSS biologists to conduct/support these studies in lieu of paying mitigation fees for habitat loss for NNSS projects that were not under the Work for Others Program (see Table 15-1, first column). The mitigation fees paid to date have provided no protection benefits to onsite tortoise populations; they have been used to support the operation of the DTCC operated by the ICR. The studies were approved because they are anticipated to reduce onsite tortoise road mortality and enhance tortoise conservation and regional recovery of the species.

In 2014, an additional six tortoises were radiotagged for inclusion in the tortoise roadside movements study, bringing the total number of tortoises in the study to 24. Analysis of the movement data and resultant recommendations to reduce road mortality are expected to be completed in 2017. Monitoring of the 60 juvenile tortoises was transferred from ICR personnel to NNSS biologists in the fall of 2013. In 2014, NNSS biologists monitored the juveniles weekly during the tortoise activity season (March through October). Health assessments were performed by ICR staff in September 2014. Nine of the juveniles died during 2014, primarily from predators. At the end of December 2014, 31 of the 60 translocated juveniles (51.7%) were still alive. The

surviving juveniles will be monitored for the next 2 to 4 years. In 2014, NNSS biologists were not requested by USGS biologists to provide support gathering data at the Rock Valley enclosures.

15.2 Biological Surveys at Proposed Project Sites

Biological surveys are performed at proposed project sites where land disturbance will occur or where significant impacts to plants and animals might occur (e.g., during the demolition of structures that may contain bird nests or the release of toxic chemicals into habitat of protected species). The goal is to minimize the adverse effects of land disturbance and other impacts on important plants and animals (see Section 15.3), their associated habitat, and important biological resources. Important biological resources include such things as cover sites, nest/burrow sites, roost sites, wetlands, or water sources that are vital to important species.

During 2014, biological surveys for 18 projects were conducted on or near the NNSS, 14 of which were on lands previously disturbed (e.g., road shoulders, existing well pads, building sites). Five of the projects had multiple sites that were surveyed. Biologists surveyed a total of 492 acres. Biologists provided to project managers written summary reports of all survey findings and mitigation recommendations, which are summarized by project in Hall et al. (2015). No important species or important biological resources were harmed by project activities in 2014, although accidental bird mortalities occurred (Table 15-2).

15.3 Important Species and Habitat Monitoring

NNSA/NFO strives to protect and conserve sensitive plant and animal species found on the NNSS and to minimize cumulative impacts to those species as a result of NNSA/NFO activities. Important species known to occur on the NNSS include 18 sensitive plants, 1 mollusk, 2 reptiles, 236 birds, and 27 mammals. They are identified in Table A-11 of *Attachment A: Site Description* (see file on the compact disc of this document). They are classified as important due to their sensitive, protected, and/or regulatory status with state or federal agencies, and they are evaluated for inclusion in long-term monitoring activities on the NNSS.

Over the past several decades, NNSA/NFO has produced numerous documents reporting the occurrence, distribution, and susceptibility to threats for predominately sensitive species on the NNSS (Wills and Ostler 2001). Field monitoring activities in 2014 that related to important NNSS plants, animals, and habitats are listed in Table 15-2. A description of the methods and a more detailed presentation of the results of these activities are reported in Hall et al. (2015). A map of all the known populations of sensitive plants on the NNSS is available at <http://www.nv.energy.gov/library/publications/Environmental/Figures/Fig11-3.pdf>.

Table 15-2. Activities conducted in 2014 for important species and habitats of the NNSS

Sensitive Plants

- NNSS biologists provided geospatial and population data sets for the 17 sensitive flowering plant species that occur on the NNSS to the Nevada Natural Heritage Program for inclusion in their statewide database.
- No field surveys were conducted in 2014 for sensitive plants due to poor growing conditions.

Migratory Birds

- Biologists ensure that migratory birds and active nests are not harmed by proposed projects and ongoing activities. During biological surveys for proposed projects conducted in 2014, no migratory bird nests, eggs, or young were found.
- Two permanent, long-term winter raptor survey routes were established and sampled in January and February. A total of 27 raptors representing 4 species were observed.
- Nine bird mortalities were documented (Figure 15-2), seven of which were due to human activities: three birds were electrocuted, three were killed by vehicles, and one died from accidental entrapment. The remaining two deaths could not be attributed to NNSA/NFO activities: one bird appeared to have been diseased, and one died from unknown causes.

Mountain Lions (*Puma concolor*)

- A collaborative effort with Kathy Longshore of the USGS to investigate the movements, habitat use, and food habits of mountain lions on the NNSS using radio-collared individuals continued in 2014. Of the four mountain lions captured and collared in 2012, only one male, NNSS7, was still alive or had a functioning collar in 2014. NNSS7 had been recaptured and fitted with a new radiocollar in June 2013. NNSS7 was tracked until November 15, 2014, when his collar released as programmed and was retrieved. Attempts to recapture him to be fitted with a second new radiocollar failed. NNSS biologists visited suspected kill sites to determine NNSS7's food habits. In 2014, NNSS7 was known to consume 21 mule deer (*Odocoileus hemionus*), 17 desert bighorn sheep (*Ovis canadensis nelsoni*), 1 juvenile bobcat (*Lynx rufus*), and 3 coyotes (*Canis latrans*).

Table 15-2. Activities conducted in 2014 for important species and habitats of the NNSS (continued)**Mountain Lions (*Puma concolor*) (continued)**

- A collaborative effort with Erin Boydston of the USGS continued in 2014 to investigate mountain lion distribution and abundance on the NNSS using remote, motion-activated cameras. Cameras collected a total of 93 photographs/video clips of mountain lions from 16 of 32 camera sites. Including the adult male radio-collared NNSS7, a minimum of four adult lions (two males, two females), one subadult male, and three kittens inhabited the NNSS during 2014 based on photographic data and mountain lion tracking efforts.

Wild Horses (*Equus caballus*)

- The annual horse census was conducted, and 42 individuals were counted, not including foals (Figure 15-3). This increase (from about 30 in 2013) is attributable to foals born in 2013 surviving to become yearlings. Mountain lion predation on foals has apparently lessened after radio-collared lion NNSS4 died in early 2013. NNSS4 is known to have killed five horse foals during 2012. High foal mortality may return, however, as other lions learn to prey upon foals. The boundary of the wild horse range on the NNSS is shown in Hall et al. (2015). Camp 17 Pond and Gold Meadows Spring continue to be important summer water sources for horses.

Mule Deer (*Odocoileus hemionus*)

- Mule deer surveys were conducted on Pahute and Rainier mesas, and the average number of deer counted was 28 deer/night, similar to the average 30 deer/night in 2013. Deer density averaged 2.0 and 1.5 deer/km² (0.8 and 0.6 deer/mi²) on Pahute Mesa and Rainier Mesa routes, respectively. Deer counts and density over the last 7 years have fluctuated and show no distinctive trends.

Desert Bighorn Sheep (*Ovis canadensis nelsoni*)

- Prior to 2009, sheep were thought to be rare on the NNSS. Motion-activated cameras set up at water sources and mountain lion kill site surveys have expanded the known distribution of sheep on and near the NNSS (Figure 15-4). Presumably they have recolonized the NNSS from other populations surrounding the NNSS. In 2014, rams, ewes, and lambs were detected using motion-activated cameras at four natural NNSS water sources in Area 29: Topopah Spring, Delirium Canyon Tanks, South Pah Canyon Tanks, and Twin Spring (see Figure A-20 in *Attachment A: Site Description*).
- A collaborative effort with Kathy Longshore of the USGS began in 2014 to collect sheep scat samples for genetic analysis to determine how sheep on the NNSS are related to surrounding sheep populations. NNSS biologists collected over 150 scat samples in 2014.
- Plans were made to conduct helicopter surveys in the fall of 2015 to census the NNSS sheep population and to capture up to 20 sheep and fit them with satellite radiocollars to track their movements.

Bats

- The recording of bat vocalizations at Camp 17 Pond was continued. Analysis of vocalizations to identify bat species will be conducted as funding is available. No analyses were conducted in 2014.
- NNSS biologists responded to five reports of bats found in buildings/structures. Live bats found are captured and released if necessary, and all roosting sites are recorded and left undisturbed whenever possible.

Reptiles (excluding desert tortoises)

- Limited reptile trapping and roadkill surveys were conducted to better define species distributions on the NNSS; 27 reptiles were captured in pitfall traps at four sampling sites and included 5 lizard and 1 snake species. Roadkill survey data from 2013 and 2014 combined identified 183 incidents of killed snakes and lizards, the majority (101) occurring during May and June. Roadkills for 2013–2014 included 8 lizard and 11 snake species.

Natural and Man-made Water Sources

- One new natural water source was discovered in the northwest corner of Area 25 on the NNSS during a mountain lion kill site survey. It is a natural formation of rock tanks, which were given the name Black Glass Canyon Tanks (see Figure A-20 of *Attachment A: Site Description*). Abundant desert bighorn sheep scat, signs of mountain lion, and scat of the large chuckwall lizard (*Sauromalus ater*) indicate it is an important wildlife resource.
- Five wildlife watering troughs, installed in 2012 to mitigate the loss of well sumps closed in 2012, continued to be monitored with motion-activated cameras to document wildlife use. A total of 13 mammal species and 9 bird species have been documented using the troughs.
- Eleven natural NNSS wetlands were monitored to document water surface area, surface flow, observed disturbances, and wildlife use and mortality. No wetlands were damaged by NNSS activities in 2014. As in previous years, a sensitive species of springsnail (*Pyrgulopsis turbatrix*) was present at Cane Spring, which is this species' only natural habitat on the NNSS.
- Three well sumps, which periodically contained radiologically contaminated groundwater in 2014 (see Chapter 5, Section 5.1.3.7.3) were monitored for wildlife use with motion-activated cameras. Monitoring was initiated to identify which species are being exposed and which may provide an exposure pathway to off site hunters who may consume them. Mule deer, mourning doves, chukar, and ducks (game species that can move off site and be harvested by hunters) were photographed at one or more of the sumps.

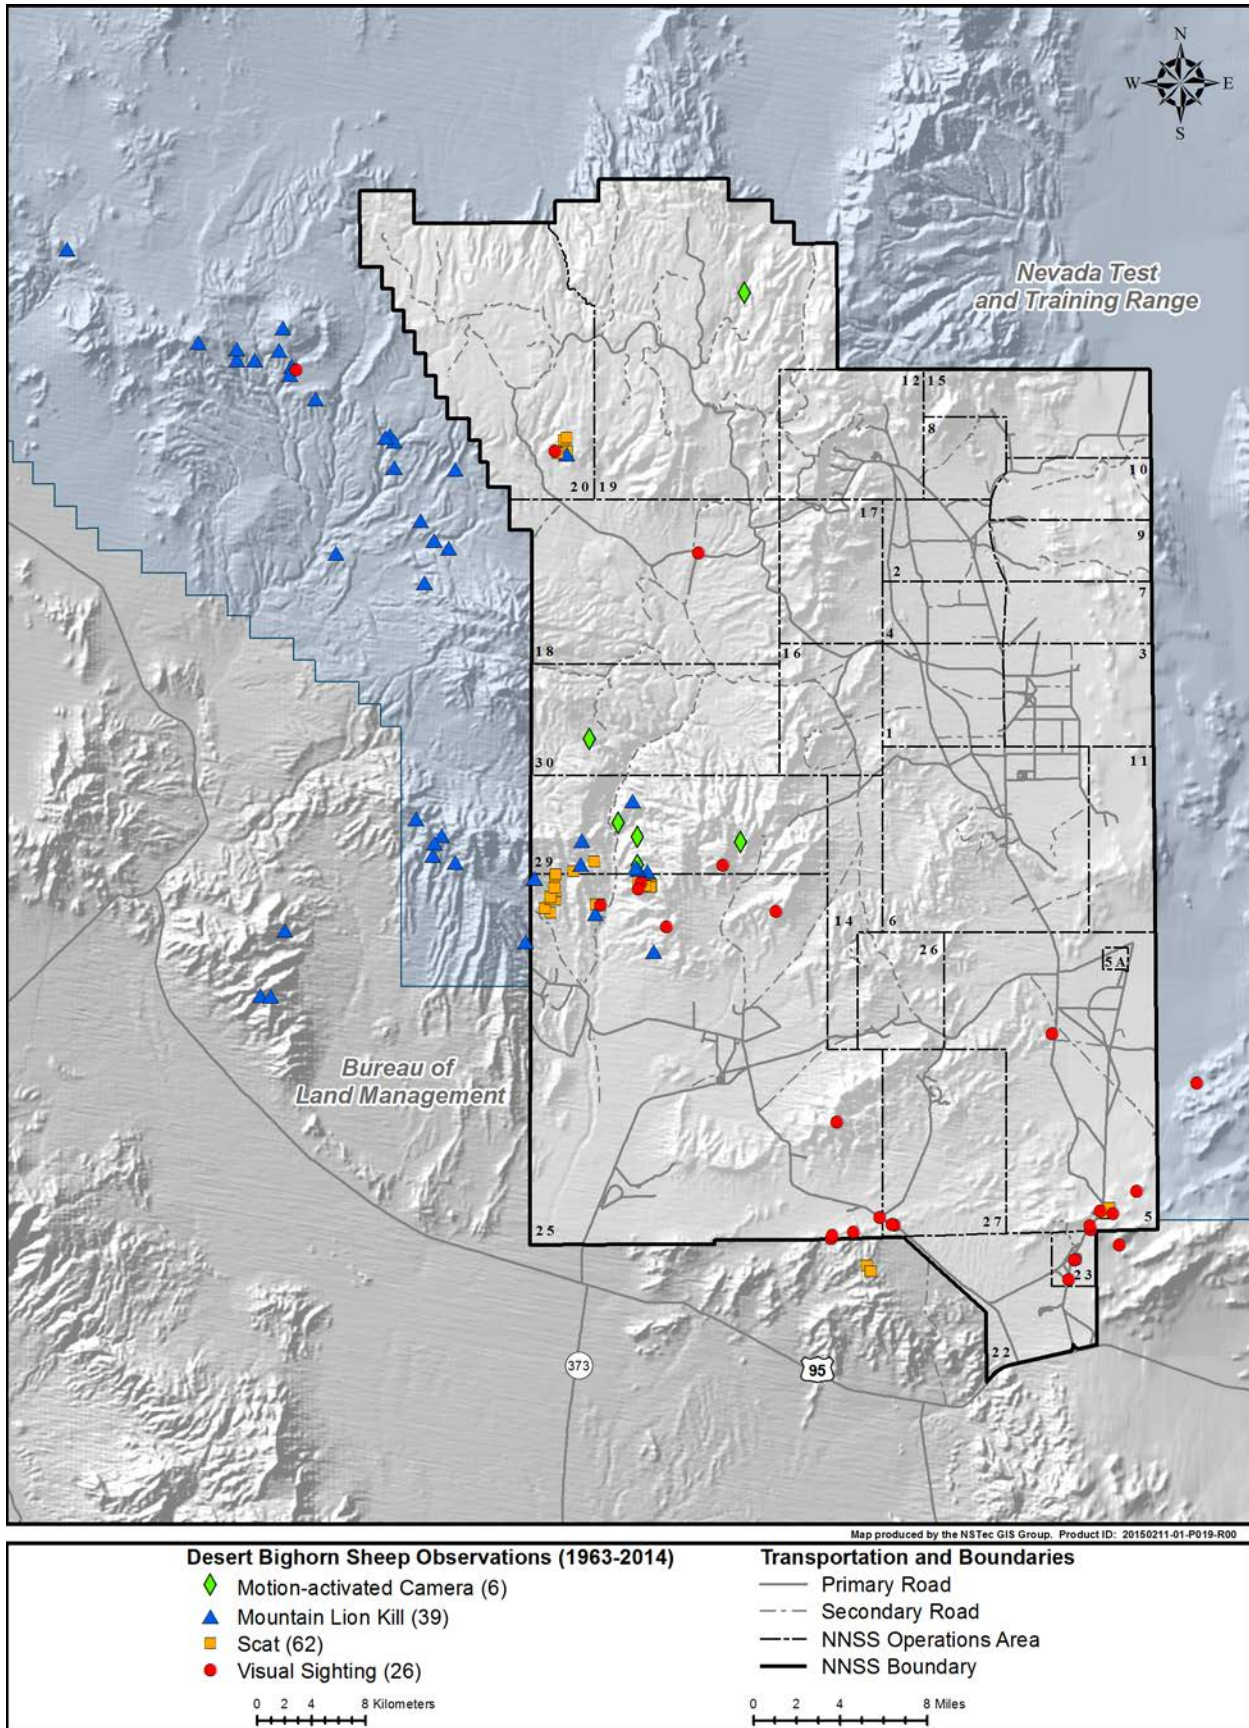

Figure 15-4. Desert bighorn sheep distribution on the NNSS and surrounding areas

15.4 *Habitat Restoration Program*

The Habitat Restoration Program revegetates disturbances and evaluates previous revegetation efforts. Sites that have been revegetated are periodically sampled, and the information obtained is used to develop site-specific revegetation plans for future restoration efforts on the NNSS. Revegetation supports the intent of Executive Order EO 13112, “Invasive Species,” to prevent the introduction and spread of non-native species and restore native species to disturbed sites. Revegetation also may qualify as mitigation for the loss of desert tortoise habitat under the current Opinion. NNSA/NFO revegetation projects include lands disturbed in desert tortoise habitat, wildland fire sites, abandoned industrial or nuclear test support sites characterized and remediated under NNSA/NFO Environmental Restoration (ER), and ER soil closure covers (or cover caps) over closed waste disposal pits.

Two previously revegetated sites on the NNSS and one on the Tonopah Test Range (TTR) were monitored in 2014. The cover cap on the U-3ax/bl disposal unit (Corrective Action Unit [CAU] 110) in Area 3, revegetated in 2000 was evaluated, and the results indicated that a stable plant community has become established on the cover cap and is capable of withstanding years of below normal precipitation.

The “92-Acre Site” at the Area 5 Radioactive Waste Management Complex (RWMC) (CAU 111), revegetated in 2011, was monitored. Hall et al. (2014) reported that remedial revegetation would be required at this site to establish a viable plant community necessary for the evapotranspirative cover cap designed for CAU 111. A small portion of the 92-Acre Site was reseeded in 2013 to evaluate various revegetation techniques, the most successful of which could be applied later to the entire site. In 2014, plant cover and density were recorded at the 2013 reseeded test plots. Hall et al. (2015) summarizes the 2014 findings and, based on them, proposes a remedial revegetation plan.

The Roller Coaster RadSafe Area (CAU 407) on TTR, revegetated in 2000, was monitored for plant cover, plant cover and density, wildlife usage, and erosion. The major concern at the site continues to be the decline in plant diversity, density, and cover. Below normal rainfall is most likely the primary reason for the declines. Erosion is being effectively controlled, and animal burrows do not appear to be causing the movement of subsurface soils to the surface.

15.5 *Wildland Fire Hazard Assessment*

A Wildland Fire Management Plan is maintained, which requires protection of site resources from wildland and operational fires. An annual vegetation survey to determine wildland fire hazards is conducted on the NNSS each spring. Survey findings are submitted to the NNSS Fire Marshal and summarized in the annual EMAC report (Hall et al. 2015). In April and May 2014, NNSS biologists visited roadside sampling stations to assess a fuel index that can range from 0 to 10 (lowest to highest risk of wildfires). The mean combined fuels index for all sampling stations was 3.83, the lowest ranking since 2004 when index values were initiated. No wildland fires were documented on the NNSS in 2014. Results from the wildland fuel surveys showed a very low risk of wildland fire due to reduced fuel loads caused by limited natural precipitation.

Chapter 16: Quality Assurance Program

Theodore J. Redding and Elizabeth Burns

National Security Technologies, LLC

Susan K. Krenzien and Irene M. Farnham

Navarro-Intera, LLC

Charles B. Davis

EnviroStat

The environmental monitoring work conducted for the U.S. Department of Energy, National Nuclear Security Administration Nevada Field Office (NNSA/NFO) is performed in accordance with the Quality Assurance Program (QAP) established by the current Management and Operations (M&O) contractor, National Security Technologies, LLC (NSTec), and with the Underground Test Area (UGTA) QAP. Both QAPs describe the methods used to ensure that quality is integrated into the monitoring work. Both QAPs comply with Title 10 Code of Federal Regulations (CFR) Part 830, Subpart A, “Quality Assurance Requirements,” and with U.S. Department of Energy (DOE) Order DOE O 414.1D, “Quality Assurance.” The 10 criteria of a quality program specified by these regulations are shown in the box above. The QAPs require a graded approach to quality for determining the level of rigor that effectively provides assurance of performance and conformance to requirements.

Required Criteria of a Quality Program

- Quality assurance program
- Personnel training and qualification
- Quality improvement process
- Documents and records
- Established work processes
- Established standards for design and verification
- Established procurement requirements
- Inspection and acceptance testing
- Management assessment
- Independent assessment

The Data Quality Objective (DQO) process developed by the U.S. Environmental Protection Agency (EPA) is generally used to provide the quality assurance (QA) structure for designing, implementing, and improving upon environmental monitoring efforts when environmental sampling and analysis are involved. Sampling and Analysis Plans are developed prior to performing an activity to ensure complete understanding of the data use objectives. Personnel are trained and qualified in accordance with company and task-specific requirements. Access to sampling locations is coordinated with organizations conducting work at or having authority over those locations in order to avoid conflicts in activities and to communicate hazards to better ensure successful execution of the work and protection of the safety and health of sampling personnel. Sample collection activities adhere to organization instructions and/or procedures that are designed to ensure that samples are representative and data are reliable and defensible. Sample shipments on site and to offsite laboratories are conducted in accordance with the U.S. Department of Transportation and International Air Transport Association regulations, as applicable. Quality control (QC) in the analytical laboratories is maintained through adherence to standard operating procedures that are based on methodologies developed by nationally recognized organizations such as the EPA, DOE, and ASTM International (formerly the American Society for Testing and Materials). Key quality-affecting procedural areas cover sample collection, preparation, instrument calibration, instrument performance checking, testing for precision and accuracy, obtaining a measurement, and laboratory data review. Data users perform reviews as required by the project-specific objectives before the data are used to support decision making.

The key elements of the environmental monitoring process work flow are listed below. Each element is designed to ensure the applicable QA requirements are implemented. A discussion of these elements follows.

- A **Sampling and Analysis Plan** (SAP) is developed using the EPA DQO process to ensure that clear goals and objectives are established for the environmental monitoring activity. The SAP is implemented in accordance with EPA, DOE, and other requirements addressing environmental, safety, and health concerns.
- **Environmental Sampling** is performed in accordance with the SAP and site work controls to ensure defensibility of the resulting data products and protection of the workers and the environment.
- **Laboratory Analyses** are performed to ensure that the resultant data meet DOE, NSTec (as the current M&O contractor), and UGTA regulation-defined requirements.

- **Data Review** is done to ensure that the SAP DQOs have been met and thereby determine whether the data are suitable for their intended purpose.
- **Assessments** are employed to ensure that monitoring operations are conducted according to procedure and that analytical data quality requirements are met in order to identify nonconforming items, investigate causal factors, implement corrective actions, and monitor for corrective action effectiveness.

16.1 Sampling and Analysis Plan

Sampling is specifically mandated to demonstrate compliance with a variety of requirements including federal and state regulations and DOE orders and standards. Developing the SAP using the DQO approach ensures that those requirements are considered in the planning stage. The following statistical concepts and controls are vital in designing and evaluating the system design and implementation.

16.1.1 Precision

Precision is the degree to which a set of observations or measurements of the same property, obtained under similar conditions, conform to themselves. Precision is a data quality indicator and is usually expressed as standard deviation, variance, or range, in either absolute or relative terms (DOE 2013).

Practically, precision is determined by comparing the results obtained from performing analyses on split or duplicate samples taken at the same time from the same location or locations very close to one another, maintaining sampling and analytical conditions as nearly identical as possible.

16.1.2 Accuracy

Accuracy refers to the degree of agreement between an observed value and an accepted reference value. Accuracy includes a combination of random error (precision) and systematic error (bias) components that are due to sampling and analytical operations. Accuracy is a data quality indicator (DOE 2013). Accuracy is monitored by performing measurements and evaluating results of control samples containing known quantities of the analytes of interest.

16.1.3 Representativeness

Representativeness is the degree to which measured analytical concentrations represent the concentrations in the medium being sampled (Stanley and Verner 1985).

At each point in the sampling and analysis process, subsamples of the medium of interest are obtained. The challenge is to ensure that each subsample maintains the character of the larger sampled population. From a field sample collection standpoint, representativeness is managed through sampling plan design and execution. Representativeness related to laboratory operations concerns the ability to appropriately subsample and characterize for analytes of interest. For example, in order to ensure representative characterization of a heterogeneous matrix (soil, sludge, solids, etc.), the sampling and/or analysis process should evaluate whether homogenization or segregation should be employed prior to sampling or analysis. Water samples are generally considered homogeneous unless observation suggests otherwise. Each air monitoring station's continuous operation at a fixed location results in representatively sampling the ambient atmosphere. Field sample duplicate analyses are additional controls allowing evaluation of representativeness and heterogeneity.

16.1.4 Comparability

Comparability refers to "the confidence with which one data set can be compared to another" (Stanley and Verner 1985). Comparability from an overall monitoring perspective is ensured by consistent execution of the sampling design concerning sample collection and handling, laboratory analyses, and data review. This is ensured through adherence to established procedures and standardized methodologies. Ongoing data evaluation compares data collected at the same locations from sampling events conducted over multiple years and produced by numerous laboratories to detect any anomalies that might occur.

16.2 Environmental Sampling

Environmental samples are collected in support of various environmental programs. Each program executes the field sampling activities in accordance with the SAP to ensure usability and defensibility of the resulting data. The key elements supporting the quality and defensibility of the sampling process and products include the following:

- Training and qualification
- Procedures and methods
- Field documentation
- Inspection and acceptance testing

16.2.1 Training and Qualification

The environmental programs ensure that personnel are properly trained and qualified prior to doing the work. In addition to procedure-specific and task-specific qualifications for performing work, training addresses environment, safety, and health aspects to ensure protection of the workers, the public, and the environment. Recurrent training is also conducted as appropriate to maintain proficiency.

16.2.2 Procedures and Methods

Sampling is conducted in accordance with established procedures to ensure consistent execution and continuous comparability of the environmental data. The analytical methods to be used are also consulted in order to ensure that, as methods are revised, sample collection is performed appropriately and that viable samples are obtained.

16.2.3 Field Documentation

Field documentation is generated for each sample collection activity. This may include chain of custody, sampling procedures, analytical methods, equipment and data logs, maps, Safety Data Sheets, and other materials needed to support the safe and successful execution and defense of the sampling effort. Chain-of-custody practices are employed from point of generation through disposal (cradle-to-grave); these are critical to the defensibility of the decisions made as a result of the sampling and analysis. Sampling data and documentation are stored and archived so they are readily retrievable for use at a later date. In many cases the data are managed in electronic data management systems. Routine assessments or surveillances are performed to ensure that sampling activities are performed in accordance with applicable requirements. Deficiencies are noted, causal factors are determined, corrective actions are implemented, and follow-up assessments are performed to ensure effective resolution. This data management approach ensures the quality and defensibility of the decisions made using analytical environmental data.

16.2.4 Inspection and Acceptance Testing

Sample collection data are reviewed for appropriateness, accuracy, and fit with historical measurements. In the case of groundwater sampling, water quality parameters are monitored during purging. Stabilization of these parameters generally indicates that the water is representative of the aquifer, at which time sample collection may begin. After a sampling activity is complete, data are reviewed to ensure the samples were collected in accordance with the SAP. Samples are further inspected to ensure that their integrity has not been compromised, either physically (leaks, tears, breakage, custody seals) or administratively (labeled incorrectly) and that they are valid for supporting the intended analyses. If concerns are raised at any point during collection, the data user, in consideration of data usability, is consulted for direction on proceeding with or canceling the subsequent analyses.

16.3 Laboratory Analyses

Samples are transported to a laboratory for analysis. Several DOE contractor organizations maintain measurement capabilities that may be used to support planning or decision-making activities. However, unless specifically authorized by NNSA/NFO or the regulator, all data used for reporting purposes are generated by a DOE- and NSTec-qualified laboratory whose services have been obtained through subcontracts. Ensuring the quality of procured laboratory services is accomplished through focus on three specific areas: (1) procurement, (2) initial and continuing assessment, and (3) data evaluation.

16.3.1 Procurement

Laboratory services are procured through subcontracts in accordance with the Competition in Contracting Act, the Federal Acquisition Regulations, the DOE Acquisition Regulations, contractor terms and conditions for subcontracting, and other relevant policies and procedures. The analytical services technical basis is codified in the DOE Quality Systems for Analytical Services (QSAS) (DOE 2013). The QSAS is based on the National Environmental Laboratory Accreditation Conference Chapter 5, “Quality Systems,” as implemented in 2005, based on International Organization for Standardization Standard ISO 17025, “General Requirements for the Competence of Testing and Calibration Laboratories.” Subcontracted laboratories must be assessed to be in compliance with the QSAS and are routinely audited under the DOE Consolidated Audit Program (DOECAP).

A request for proposal (RFP) is posted to the government website, laboratory responses are evaluated, and subcontracts awarded. The RFP cites the QSAS and DOECAP participation as base requirements and addresses site-specific conditions. Multiple laboratories may receive a subcontract through one RFP.

The laboratories are primarily those providing a wide range of analytical services to DOE. Other services can be subcontracted by the laboratory (i.e., lower-tier subcontractor) or contracted directly from a vendor. In either case, requirements are established for the specific services provided.

The subcontract places numerous requirements on the laboratory, including the following:

- Maintaining the following documents:
 - A Quality Assurance Plan and/or Manual describing the laboratory’s policies and approach to the implementation of QA requirements
 - An Environment, Safety, and Health Plan
 - A Waste Management Plan
 - Procedures pertinent to subcontract scope
- The ability to generate data deliverables, both hard copy reports and electronic files
- Responding to all data quality questions in a timely manner
- Mandatory participation in proficiency testing programs
- Maintaining specific licenses, accreditations, and certifications
- Conducting internal audits of laboratory operations as well as audits of vendors
- Allowing external audits by DOECAP and NNSA/NFO contractors and providing copies of other audits considered by NSTec to be comparable and applicable

16.3.2 Initial and Continuing Assessment

An initial assessment is made during the RFP process, including a pre-award audit. If an acceptable audit has not been performed within the past year, NSTec will consider performing an audit (or participating in a DOECAP audit) of those laboratories awarded the contract. NSTec will not initiate work with a laboratory without authorized approval from those NSTec personnel responsible for ensuring vendor acceptability.

A continuing assessment consists of the ongoing monitoring of a laboratory's performance against contract terms and conditions, of which the technical specifications are a part. Tasks supporting continuing assessment are as follows:

- Conducting regular audits or participating in evaluation of DOECAP audit products
- Monitoring for continued successful participation in proficiency testing programs such as:
 - National Institute of Standards and Technology Radiochemistry Intercomparison Program
 - Studies that support certification by the State of Nevada or appropriate regulatory authority for analyses performed in support of compliance monitoring
- Routine ongoing monitoring of the laboratory's adherence to the quality requirements

16.3.3 Data Evaluation

Data products are continuously evaluated for compliance with contract terms and specifications. This primarily involves review of the data against the specified analytical method to determine the laboratory's ability to adhere to the QA/QC requirements, as well as an evaluation of the data against the DQOs. This activity is discussed in further detail in Section 16.4. Any discrepancies are documented and resolved with the laboratory, and continuous assessment tracks the recurrence and efficacy of corrective actions.

16.4 Data Review

A systematic approach to thoroughly evaluating the data products generated from an environmental monitoring effort is essential for understanding and sustaining the quality of data collected under the program. This allows the programs to determine whether the DQOs established in the planning phase were achieved and whether the monitoring design performed as intended or requires review.

Because decisions are based on environmental data, and the effectiveness of operations is measured at least in part by environmental data, reliable, accurate, and defensible records are essential. Detailed records that must be kept include temporal, spatial, numerical, geotechnical, chemical, and radiological data as well as all sampling, analytical, and data review procedures used. Failure to maintain these records in a secure but accessible form may result in exposure to legal challenges and the inability to respond to demands or requests from regulators and other interested organizations.

An electronic data management system is a key tool used by many programs for achieving standardization and integrity in managing environmental data. The primary objective is to store and manage in an easily and efficiently retrievable form unclassified environmental data that are directly or indirectly tied to monitoring events. This may include information on monitoring system construction (groundwater wells, ambient air monitoring), and analytical, geotechnical, and field parameters at the Nevada National Security Site. Database integrity and security are enforced through the assignment of varying database access privileges commensurate with an employee's database responsibilities.

16.4.1 Data Verification

Data verification is defined as a subcontract compliance and completeness review to ensure that all laboratory data and sample documentation are present and complete. Additional critical sampling and analysis process information is also reviewed at this stage, which may include, but is not limited to, sample preservation and temperature, defensible chain-of-custody documentation and integrity, and analytical hold-time compliance. Data verification also ensures that electronic data products correctly represent the sampling and/or analyses performed, and includes evaluation of QC sample results.

16.4.2 Data Validation

Data validation supplements verification and is a more thorough process of analytical data review to better determine if the data meet the analytical and project requirements. Data validation ensures that the reported results correctly represent the sampling and analyses performed, determines the validity of the reported results, and assigns data qualifiers (or "flags"), if required.

16.4.3 Data Quality Assessment (DQA)

DQA is a scientific and statistical evaluation to determine if the data obtained from environmental operations are of the right type, quality, and quantity to support their intended use. The DQA includes reviewing data for accuracy, representativeness, and fit with historical measurements to ensure that the data will support their intended uses.

16.5 Assessments

The overall effectiveness of the environmental program is determined through routine surveillance and assessments of work execution as well as review of the program requirements. Deficiencies are identified, causal factors are investigated, corrective actions are developed and implemented, and follow-on monitoring is performed to ensure effective resolution. The assessments discussed below are broken down into general programmatic and focused measurement data areas.

16.5.1 Programmatic

Assessments and audits under this category include evaluations of the work planning, execution, and performance activities. Personnel independent of the work activity perform the assessments to evaluate compliance with established requirements and report on the identified deficiencies. Organizations responsible for the activity are required to develop and implement corrective actions, with the concurrence of the deficiency originator or recognized subject matter expert. NNSA/NFO contractors maintain companywide issues tracking systems to manage assessments, findings, and corrective actions.

16.5.2 Measurement Data

This type of assessment includes routine evaluation of data generated from analyses of QC samples. QC sample data are used to monitor the analytical control on a given batch of samples and are indicators over time of potential biases in laboratory performance. Discussions of the 2014 results for field duplicates, laboratory control samples, blank analyses, matrix spikes, and proficiency testing programs are provided, and summary tables are included below.

16.5.2.1 Field Duplicates

Samples obtained at nearly the same locations and times as initial samples are termed field duplicates. These are used to evaluate the overall precision of the measurement process, including small-scale heterogeneity in the medium (air, water, or direct radiation) being sampled as well as analytical and sample preparation variation. The absolute relative percent difference (RPD) compares the absolute difference of initial and field duplicate measurements with the average of the two measurements (Table 16-1, footnote c); it is computed only from pairs for which both values are above their respective minimum detectable concentrations (MDCs). An absolute RPD less than 25% for any sample and its field duplicate is considered acceptable. The relative error ratio (RER) compares the absolute difference of initial and field duplicate measurements to the laboratory's reported analytical uncertainty (Table 16-1, footnote d). An RER less than 3 for any sample and its field duplicate is considered acceptable.

The average absolute RPD and average RER values for all 2014 radiological air and water samples are shown in Table 16-1. They generally fall in ranges typical for prior years. The higher average absolute RPDs (those greater than 25) are associated with two types of phenomena. RPDs for actinides in air, in particular, and consequently for gross alpha in air, can be elevated when one sampler of a pair intercepts a particle with high americium (Am) or plutonium (Pu), while the other sampler in the pair had a typical background value. For example, RPDs for ^{238}Pu and $^{239+240}\text{Pu}$ were 76.2 and 48.8. Also, higher average absolute RPDs are often associated with relatively few pairs having both values above their MDCs, as low-level measurements are typically "noisier" than higher-level measurements (again, ^{238}Pu in 2014). The average RER can also be affected by particulates, as with $^{239+240}\text{Pu}$ in air (average RER = 1.83 in 2014). Also, both averages can be variable when there are smaller numbers of pairs overall.

As noted in Chapter 4, beginning in 2014, air filters have been deployed biweekly rather than weekly at all stations, analyzed for gross alpha and gross beta, and then composited quarterly rather than monthly for the other analytes. As an additional QA measure related to this change, for the first two quarters additional filters were deployed weekly

and composited monthly at three stations. Field duplicate (FD) values along with pseudo-errors and pseudo-MDCs were calculated from these additional filters. These generally show no differences, with the exception of ^7Be , for which the original RPD and RER values were 19.5 and 3.07 respectively. This is due to higher values in the monthly composites compared with the quarterly composites, apparently resulting from the short half-life (53 days) of ^7Be . When a decay correction is applied to the monthly values before averaging, the average absolute RPD and RER for all pairs become 4.8 and 0.67 (Table 16-1) respectively, much more consistent with historical values.

Table 16-1. Summary of field duplicate samples for 2014

Analyte	Medium	Number of Duplicate Pairs ^(a)	Number of Pairs > MDC ^(b)	Average Absolute RPD ^(c) of Pairs > MDC	Average Absolute RER ^(d) of All Pairs
Environmental Monitoring Samples					
Gross alpha	Air	91	50	20.4	0.82
Gross beta	Air	91	91	5.0	0.78
Tritium	Air	54	0	-	0.71
^{241}Am	Air	12	0	-	0.90
^{238}Pu	Air	12	2	76.2	0.76
$^{239+240}\text{Pu}$	Air	12	8	48.8	1.83
$^{233+234}\text{U}$	Air	8	8	21.3	1.36
$^{235+236}\text{U}$	Air	8	5	28.5	0.90
^{238}U	Air	8	8	24.9	1.61
$^7\text{Be}^{(e)}$	Air	12	12	4.8	0.67
^{137}Cs	Air	12	0	-	0.75
$^{40}\text{K}^{(e)}$	Air	12	5	46.0	1.27
Gross alpha	Water	5	5	17.2	0.71
Gross beta	Water	5	5	17.2	1.05
Tritium	Water	12	2	2.8	0.69
TLD	Ambient Radiation	440	NA ^(f)	3.0	0.28
Underground Test Area (UGTA) Samples					
Gross alpha	Water	32	8	17	0.20
Gross beta	Water	32	11	6.4	0.41
Tritium	Water	44	23	4.8	0.32

(a) Represents the number of field duplicates reported for evaluating precision.

(b) Represents the number of field duplicate–field sample pairs with both values above their MDCs. If either the field sample or duplicate was below the MDC, the RPD was not determined. This does not apply to thermoluminescent dosimeter (TLD) measurements; because TLDs virtually always detect ambient background radiation, MDCs are not computed.

(c) Represents the average absolute RPD calculated as follows:

$$\text{Absolute RPD} = \frac{|S - D|}{(D + S)/2} \times 100$$

Where: S = Sample result
D = Duplicate result

(d) Represents the absolute RER, determined by the following equation, which is used to determine whether a sample result and the associated field duplicate result differ significantly when compared to their respective 1 sigma uncertainties (i.e., measurement standard deviation). The RER is calculated for all sample and field duplicate pairs reported without regard to the MDC.

$$\text{Absolute RER} = \frac{|S - D|}{\sqrt{(SD_S)^2 + (SD_D)^2}}$$

Where: S = Sample result
D = Duplicate result
SD_S = Standard deviation of the sample result
SD_D = Standard deviation of the duplicate result

(e) ^7Be and ^{40}K are naturally occurring analytes included for quality assessment of the gamma spectroscopy analyses.

(f) Not applicable

16.5.2.2 Laboratory Control Samples (LCSs)

An LCS is prepared from a sample matrix verified to be free from the analytes of interest, and then spiked with verified known amounts of analytes or a material containing known and verified amounts of analytes. The LCS is generally used to establish intra-laboratory or analyst-specific precision and bias or to assess the performance of all or a portion of the measurement system (DOE 2013).

The results are calculated as a percentage of the true value (i.e., percent recovery), and must fall within established control limits to be considered acceptable. If the LCS recovery falls outside control limits, evaluation for potential sample data bias is necessary. The numbers of the 2014 LCSs analyzed and within control limits are summarized in Table 16-2. There were no systemic issues identified in 2014 by LCS recovery data, and no failures that invalidated the associated sample data.

Table 16-2. Summary of LCSs for 2014

Analyte	Matrix	Number of LCS Results Reported	Number Within Control Limits	Control Limits (%)
Environmental Monitoring Samples				
Tritium	Air	51	51	75–125

16.5.2.3 Blank Analysis

In general terms, a blank is a sample that has not been exposed to the analyzed sample stream, and is analyzed in order to monitor contamination that might be introduced during sampling, transport, storage, or analysis. The blank is subjected to the usual analytical and measurement process to establish a zero baseline or background value, and is sometimes used to adjust or correct routine analytical results (DOE 2013). Blanks are processed simultaneously with and under the same conditions as samples through all steps of the analytical procedures. The following discusses the blanks routinely used during environmental monitoring activities.

- A trip blank is a sample of analyte-free media taken from the laboratory to the sampling site and returned to the laboratory unopened. A trip blank is used to document contamination attributable to shipping and field handling procedures. This type of blank is useful in documenting contamination of volatile organics samples (DOE 2013).
- An equipment blank is a sample of analyte-free media that has been used to rinse common sampling equipment to check effectiveness of decontamination procedures (DOE 2013).
- A field blank is prepared in the field by filling a clean container with purified water (appropriate for the target analytes) and appropriate preservative, if any, for the specific sampling activity being undertaken. The field blank is used to indicate the presence of contamination due to sample collection and handling (DOE 2013).
- A method blank is a sample of a matrix similar to the associated sample batch in which no target analytes or interferences are present at concentrations that would impact the sample analyses results (DOE 2013). Method blank data are summarized in Table 16-3.

There were no systemic issues and no failures that required invalidating the associated sample data identified in 2014 by the blank data.

Table 16-3. Summary of laboratory blank samples for 2014

Analyte	Matrix	Number of Blank Results Reported	Number of Results < MDC
Environmental Monitoring Samples			
Tritium	Air	70	69

Tritium	Water	22	22

16.5.2.4 Matrix Spike Analysis

A matrix spike is a sample spiked with a known concentration of analyte. This spike sample is subjected to the same sample preparation and analysis as the original environmental sample. The matrix spike is used to indicate if the matrix (e.g., soil, water with sediment) interferes with the analytical results. Matrix spike analyses were conducted for samples in 2014, and there were no issues identified by the analysis data (Table 16-4).

Table 16-4. Summary of matrix spike samples for 2014

Analyte	Matrix	Number of Matrix Spikes Reported	Number Within Control Limits	Control Limits (%)
Environmental Monitoring Samples				
Tritium	Air	14	14	60–140
Gross alpha	Water	8	8	60–140
Gross beta	Water	8	8	60–140

UGTA Samples				
Gross alpha	Water	21	21	60–140
Gross beta	Water	21	21	60–140
Tritium	Water	26	26	60–140

16.5.2.5 Proficiency Testing Program Participation

All contracted laboratories are required to participate in proficiency testing programs. Laboratory performance supports decisions on work distribution and may also be a basis for state certifications. Table 16-5 presents the 2014 results for the laboratory performance in the March and August studies of the Mixed Analyte Performance Evaluation Program (MAPEP) (<http://www.id.energy.gov/resl/mapep/mapepreports.html>) administered by the Radiological and Environmental Sciences Laboratory of the Idaho National Laboratory.

Table 16-6 shows the summary of inter-laboratory comparison sample results for the NSTec Radiological Health Dosimetry Group. The DOE Standard DOE-STD-1095-2011, “Department of Energy Laboratory Accreditation for External Dosimetry,” establishes the methodology for determining acceptable performance testing of dosimeter systems. It also establishes the technical basis for performance testing and the testing categories and performance criteria, which are outlined in the American National Standards Institute/Health Physics Society (ANSI/HPS) N13.11-2009, “American National Standard for Dosimetry–Personnel Dosimetry Performance–Criteria for Testing,” and in ANSI/HPS N13.32-2008, “An American National Standard, Performance Testing of Extremity Dosimeters.” The Dosimetry Group participated in the Battelle Pacific Northwest National Laboratory proficiency testing program during the course of the year.

Chapter 17: Quality Assurance Program for the Community Environmental Monitoring Program

Craig Shadel

Desert Research Institute

The Community Environmental Monitoring Program (CEMP) Quality Assurance Management and Assessment Plan (QAMAP) (Desert Research Institute 2009) was followed for the collection and analysis of radiological air and water data presented in Chapter 7 of this report. The CEMP QAMAP ensures compliance with U.S. Department of Energy (DOE) Order DOE O 414.1D, “Quality Assurance,” which implements a quality management system, ensuring the generation and use of quality data. This QAMAP addresses the following items previously defined in Chapter 16:

- Data Quality Objectives (DQOs)
- Sampling plan development appropriate to satisfy the DQOs
- Environmental health and safety
- Sampling plan execution
- Sample analyses
- Data review
- Continuous improvement

17.1 Data Quality Objectives (DQOs)

The DQO process is a strategic planning approach that is used to plan data collection activities. It provides a systematic process for defining the criteria that a data collection design should satisfy. These criteria include when and where samples should be collected, how many samples to collect, and the tolerable level of decision errors for the study. DQOs are unique to the specific data collection or monitoring activity, and follow similar guidelines for onsite activities where applicable as discussed in Chapter 16.

17.2 Measurement Quality Objectives (MQOs)

The MQOs are basically equivalent to DQOs for analytical processes. The MQOs provide direction to the laboratory concerning performance objectives or requirements for specific method performance characteristics. Default MQOs are established in the subcontract with the laboratory, but may be altered in order to satisfy changes in the DQOs. The MQOs for the CEMP project are described in terms of precision, accuracy, representativeness, completeness, and comparability requirements. These terms are defined and discussed in Section 16.1 for onsite activities.

17.3 Sampling Quality Assurance Program

Quality Assurance (QA) in field operations for the CEMP includes sampling assessments, surveillances, and oversight of the following supporting elements:

- The sampling plan, DQOs, and field data sheets accompanying the sample package
- Database support for field and laboratory results, including systems for long-term storage and retrieval
- A training program to ensure that qualified personnel are available to perform required tasks

Sample packages include the following items:

- Station manager checklist confirming all observable information pertinent to sample collection
- An Air Surveillance Network Sample Data Form documenting air sampler parameters, collection dates and times, and total sample volumes collected
- Chain-of-custody forms

This managed approach to sampling ensures that the sampling is traceable and enhances the value of the final data available to the project manager. The sample package also ensures that the Community Environmental Monitor (CEM) station manager (see Chapter 7 for a description of CEMs) has followed proper procedures for sample collection. The CEMP Project Manager or QA Officer routinely performs assessments of the station managers and field monitors to ensure that standard operating procedures and sampling protocols are being followed properly.

Data obtained in the course of executing field operations are entered in the documentation accompanying the sample package during sample collection and in the CEMP database along with analytical results upon their receipt and evaluation.

Completed sample packages are kept as hard copy in file archives. Analytical reports are kept as hard copy in file archives as well as on read-only compact discs by calendar year. Analytical reports and databases are protected and maintained in accordance with the Desert Research Institute's Computer Protection Program.

17.4 Laboratory QA Oversight

The CEMP ensures that DOE O 414.1D requirements are met with respect to laboratory services through review of the vendor laboratory policies formalized in a Laboratory Quality Assurance Plan (LQAP) (Testamerica, Inc., 2012). The CEMP is assured of obtaining quality data from laboratory services through a multifaceted approach, involving specific procurement protocols, the conduct of quality assessments, and requirements for selected laboratories to have an acceptable QA Program. These elements are discussed below.

17.4.1 Procurement

Laboratory services are procured through subcontracts. The subcontract establishes the technical specifications required of the laboratory and provides the basis for determining compliance with those requirements and evaluating overall performance. The subcontract is awarded on a "best value" basis as determined by pre-award audits. The prospective vendor is required to provide a review package to the CEMP that includes the following items:

- All procedures pertinent to subcontract scope
- Environment, Safety, and Health Plan
- LQAP
- Example deliverables (hard copy and/or electronic)
- Proficiency testing (PT) results from the previous year from recognized PT programs
- Résumés
- Facility design/description
- Accreditations and certifications
- Licenses
- Audits performed by an acceptable DOE program covering comparable scope
- Past performance surveys
- Pricing

CEMP evaluates the review package in terms of technical capability. Vendor selection is based solely on these capabilities and not biased by pricing.

17.4.2 Initial and Continuing Assessment

An initial assessment of a laboratory is managed through the procurement process above, including a pre-award audit. Pre-award audits are conducted by the CEMP (usually by the CEMP QA Officer). The CEMP does not initiate work with a laboratory without approval of the CEMP Program Manager.

A continuing assessment of a selected laboratory involves ongoing monitoring of a laboratory's performance against the contract terms and conditions, of which technical specifications are a part. The following tasks support continuing assessment:

- Tracking schedule compliance
- Reviewing analytical data deliverables
- Monitoring the laboratory's adherence to the LQAP
- Conducting regular audits
- Monitoring for continued successful participation in approved PT programs

17.4.3 Laboratory QA Program

The laboratory policies and approach to the implementation of DOE O 414.1D must be verified in an LQAP prepared by the laboratory. The elements of an LQAP required for the CEMP are similar to those required by National Security Technologies, LLC, for onsite monitoring, and are described in Section 16.3.

17.5 Data Review

Essential components of process-based QA are data checks, verification, validation, and data quality assessment to evaluate data quality and usability.

Data Checks – Data checks are conducted to ensure accuracy and consistency of field data collection operations prior to and upon data entry into CEMP databases and data management systems.

Data Verification – Data verification is defined as a subcontract compliance and completeness review to ensure that all laboratory data and sample documentation are present and complete. Sample preservation, chain-of-custody, and other field sampling documentation shall be reviewed during the verification process. Data verification ensures that the reported results entered in CEMP databases correctly represent the sampling and/or analyses performed and includes evaluation of quality control (QC) sample results.

Data Validation – Data validation is the process of reviewing a body of analytical data to determine if it meets the data quality criteria defined in operating instructions. Data validation ensures that the reported results correctly represent the sampling and/or analyses performed, determines the validity of the reported results, and assigns data qualifiers (or “flags”), if required. The process of data validation consists of the following:

- Evaluating the quality of the data to ensure that all project requirements are met
- Determining the impact on data quality of those requirements if they are not met
- Verifying compliance with QA requirements
- Checking QC values against defined limits
- Applying qualifiers to analytical results in the CEMP databases for the purposes of defining the limitations in the use of the reviewed data

Operating instructions, procedures, applicable project-specific work plans, field sampling plans, QA plans, analytical method references, and laboratory statements of work may all be used in the process of data validation. Documentation of data validation includes checklists, qualifier assignments, and summary forms.

Data Quality Assessment (DQA) – DQA is the scientific evaluation of data to determine if the data obtained from environmental data operations are of the right type, quality, and quantity to support their intended use. DQA review is a systematic review against pre-established criteria to verify that the data are valid for their intended use.

17.6 QA Program Assessments

The overall effectiveness of the QA Program is determined through management and independent assessments as defined in the CEMP QAMAP. These assessments evaluate the plan execution workflow (sampling plan development and execution, chain-of-custody, sample receiving, shipping, subcontract laboratory analytical activities, and data review) as well as program requirements as it pertains to the organization.

17.7 2014 Sample QA Results

QA assessments were performed by the CEMP, including the laboratories responsible for sample analyses. These assessments ensure that sample collection procedures, analytical techniques, and data provided by the subcontracted laboratories comply with CEMP requirements. Data were provided by Testamerica Laboratories and the University of Nevada, Las Vegas, Radiation Services Laboratory (gross alpha/beta and gamma spectroscopy data); Mirion Technologies (thermoluminescent dosimeter [TLD] data); and the University of Miami Tritium Laboratory (tritium data). A brief discussion of the 2014 results for field duplicates, laboratory control samples, blank analyses, and inter-laboratory comparison studies is provided along with summary tables within this section. The 2014 CEMP radiological air and water monitoring data are presented in Chapter 7.

17.7.1 Field Duplicates (Precision)

A field duplicate is a sample collected, handled, and analyzed following the same procedures as the primary sample. The relative percent difference (RPD) between the field duplicate result and the corresponding field sample result is a measure of the variability in the process caused by the sampling uncertainty (matrix heterogeneity, collection variables, etc.) and measurement uncertainty (field and laboratory) used to arrive at a final result. The average absolute RPD, expressed as a percentage, was determined for the calendar year 2014 samples and is listed in Table 17-1. An RPD of zero indicates a perfect duplication of results of the duplicate pair, whereas an RPD greater than 100% generally indicates that a duplicate pair falls beyond QA requirements and is not considered valid for use in data interpretation. These samples are further evaluated to determine the reason for QA failure and if any corrective actions are required. Overall, the RPD values for all analyses indicate very good results, with only two alpha duplicates exceeding an RPD of 100%.

Table 17-1. Summary of field duplicate samples for CEMP monitoring in 2014

Analysis	Matrix	Number of Samples Reported ^(a)	Number of Samples Reported above MDC ^(b)	Average Absolute RPD of those above MDC (%) ^(c)
Gross Alpha	Air	50	50	47.2
Gross Beta	Air	50	50	31.3
Gamma – Beryllium-7	Air	11	7	63.3
Tritium	Water	1	0	NA ^(d)
TLDs	Ambient Radiation	12	NA	3.4

- (a) Represents the number of field duplicates reported for the purpose of monitoring precision. If an associated field sample was not processed, the field duplicate was not included in this table.
- (b) Represents the number of field duplicate–field sample result sets reported above the minimum detectable concentration (MDC) (MDC is not applicable for TLDs). If either the field sample or its duplicate was reported below the detection limit, the precision was not determined.
- (c) Reflects the average absolute RPD calculated for those field duplicates reported above the MDC.
- (d) Not applicable.

The absolute RPD calculation is as follows:

$$Absolute\ RPD = \frac{|FD - FS|}{(FD + FS) / 2} \times 100\%$$

Where: FD = Field duplicate result
FS = Field sample result

17.7.2 Laboratory Control Samples (Accuracy)

Laboratory control samples (LCSs) (also known as matrix spikes) are performed by the subcontract laboratory to evaluate analytical accuracy, which is the degree of agreement of a measured value with the true or expected value. Samples of known concentration are analyzed using the same methods as employed for the project samples. The results are determined as the measured value divided by the true value, expressed as a percentage. To be considered valid, the results must fall within established control limits (or percentage ranges) for further analyses to be performed. The LCS results obtained for 2014 are summarized in Table 17-2. The LCS results were satisfactory, with all samples falling within control parameters for the air sample matrix.

Table 17-2. Summary of laboratory control samples (LCSs) for CEMP monitoring in 2014

Analysis	Matrix	Number of LCS Results Reported	Number Within Control Limits ^(a)
Gross Alpha	Air	38	38
Gross Beta	Air	38	38
Gamma	Air	8	8
Tritium	Water	1	1

(a) Control limits are as follows: 75% to 125% for gross alpha, 75% to 125% for gross beta, 87% to 120% for gamma (¹³⁷Cs, ⁶⁰Co, ²⁴¹Am), and 80% to 120% for tritium.

17.7.3 Blank Analysis

Laboratory blank sample analyses are essentially the opposite of LCSs discussed in Section 17.7.2. These samples do not contain any of the analyte of interest. Results of these analyses are expected to be “zero,” or, more accurately, below the MDC of a specific procedure. Blank analysis and control samples are used to evaluate overall laboratory procedures, including sample preparation and instrument performance. The laboratory blank sample results obtained for 2014 are summarized in Table 17-3. The laboratory blank results were satisfactory with only one of the alpha and one of the beta blank samples (3%) outside of control parameters for the air sample matrix.

Table 17-3. Summary of laboratory blank samples for CEMP monitoring in 2014

Analysis	Matrix	Number of Blank Results Reported	Number within Control Limits ^(a)
Gross Alpha	Air	38	37
Gross Beta	Air	38	37
Gamma	Air	8	8
Tritium	Water	1	1

(a) Control limit is less than the MDC.

17.7.4 Inter-laboratory Comparison Studies

Inter-laboratory comparison studies are conducted by the subcontracted laboratories to evaluate their performance relative to other laboratories providing the same service. These types of samples are commonly known as “blind” samples, in which the expected values are known only to the program conducting the study. The analyses are evaluated and, if found satisfactory, the laboratory is certified that its procedures produce reliable results. The inter-laboratory comparison sample results obtained for 2014 are summarized in Tables 17-4 and 17-5.

Table 17-4 shows the summary of inter-laboratory comparison sample results for the subcontract radiochemistry laboratories. The laboratories participated in either the QA Program administered by Environmental Research Associates (ERA) and/or the Mixed Analyte Performance Evaluation Program (MAPEP) for gross alpha, gross

beta, and gamma analyses. The subcontract tritium laboratory participated in the International Atomic Energy Agency (IAEA) tritium inter-laboratory comparison study. The subcontractors performed very well during the year by passing all of the parameters analyzed.

Table 17-4. Summary of inter-laboratory comparison samples of the subcontract radiochemistry and tritium laboratories for CEMP monitoring in 2014

Analysis	Matrix	MAPEP, ERA, and IAEA Results	
		Number of Results Reported	Number Within Control Limits ^(a)
Gross Alpha	Air	4	4
Gross Beta	Air	4	4
Gamma	Air	4	4
Tritium	Water	6	6

(a) Control limits are determined by the individual inter-laboratory comparison study.

Table 17-5 shows the summary of the in-house performance evaluation results conducted by the subcontract dosimetry group. This internal evaluation was based on National Voluntary Laboratory Accreditation Program (NVLAP) criteria and was performed biannually. The dosimetry group performed very well during the year, passing 12 out of 12 TLDs analyzed.

Table 17-5. Summary of inter-laboratory comparison TLD samples of the subcontract dosimetry group for CEMP monitoring in 2014

Analysis	Matrix	Number of Results Reported	Number Within Control Limits ^(a)
TLDs	Ambient Radiation	12	12

(a) Based upon NVLAP criteria; absolute value of the bias plus one standard deviation < 0.3.

Appendix A: Las Vegas Area Support Facilities

Desiree M. Demers, Delane P. Fitzpatrick-Maul, Jennifer M. Mercadante, Phyllis M. Radack, and Ronald W. Warren

National Security Technologies, LLC

The U.S. Department of Energy, National Nuclear Security Administration Nevada Field Office (NNSA/NFO) manages two facilities in Clark County, Nevada, that support NNSA/NFO missions on and off the Nevada National Security Site (NNSS). They include the North Las Vegas Facility (NLVF) and the Remote Sensing Laboratory–Nellis (RSL–Nellis) (Figure A-1). This appendix describes all environmental monitoring and compliance activities conducted in 2014 at these support facilities.

A.1 North Las Vegas Facility

The NLVF is a fenced complex composed of 31 buildings that house much of the NNSS project management, diagnostic development and testing, design, engineering, and procurement personnel. The 32-hectare (80-acre) facility is located along Losee Road, a short distance west of Interstate 15 (Figure A-1). The facility is buffered on the north, south, and east by general industrial zoning. The western border separates the property from fully developed, single-family residential-zoned property. The NLVF is a controlled-access facility. Environmental compliance and monitoring activities associated with this facility in 2014 included the maintenance of one air quality operating permit, one wastewater permit, one National Pollutant Discharge Elimination System (NPDES) permit, one Spill Prevention, Control, and Countermeasure (SPCC) Plan, and one hazardous materials permit (see Chapter 2, Table 2-13 for a list of all NNSA/NFO permits). NNSA/NFO also monitors tritium in air and ambient gamma-emissions to comply with federal radiation protection regulations, although this monitoring is not required by any city or state permits.

A.1.1 Air Quality and Protection

Sources of air pollutants at the NLVF are regulated by the Source 657 Minor Source Permit issued by the Clark County Department of Air Quality (DAQ) for the emission of criteria pollutants (see Glossary, Appendix B). These pollutants include particulate matter (PM), nitrogen oxide (NO_x), carbon monoxide (CO), sulfur dioxide (SO₂), and volatile organic compounds (VOCs). Because the NLVF is considered a “true minor source,” there is no requirement to report hazardous air pollutants (HAPs) (see Glossary, Appendix B). The regulated sources of emissions at the NLVF include an abrasive blaster, diesel generators, a fire pump, cooling towers, and boilers. The DAQ requires an annual emissions inventory of criteria air pollutants. The 2014 emissions inventory, which reported the estimated quantities shown in Table A-1, was submitted to the DAQ on March 12, 2014.

Table A-1. Summary of air emissions for the NLVF in 2014

Parameter	Criteria Pollutant (Tons/yr) ^(a)					
	PM10 ^(b)	PM2.5 ^(c)	NO _x	CO	SO ₂	VOC
PTE ^(d)	0.96	0.32	8.08	1.63	0.34	0.35
Actual ^(e)	0.13	0.04	0.67	0.18	0.03	0.03
Total Emissions = 1.08 Actual, 11.68 PTE						

(a) 1 ton equals 0.91 metric tons

(b) Particulate matter equal to or less than 10 microns in diameter

(c) Particulate matter equal to or less than 2.5 microns in diameter

(d) Potential to emit: The quantity of criteria air pollutant that facilities/pieces of equipment would emit annually if they were operated for the maximum number of hours at the maximum production rate specified in the air permit

(e) Emissions based on calculations using actual hours of operation for each piece of equipment

Clark County air regulations specify that the opacity from any emission unit may not exceed the Clean Air Act National Ambient Air Quality Standards (NAAQS) opacity limit of 20% for more than 6 consecutive minutes. The NLVF air permit requires that at least one visual emissions observation be performed each week for the boilers,

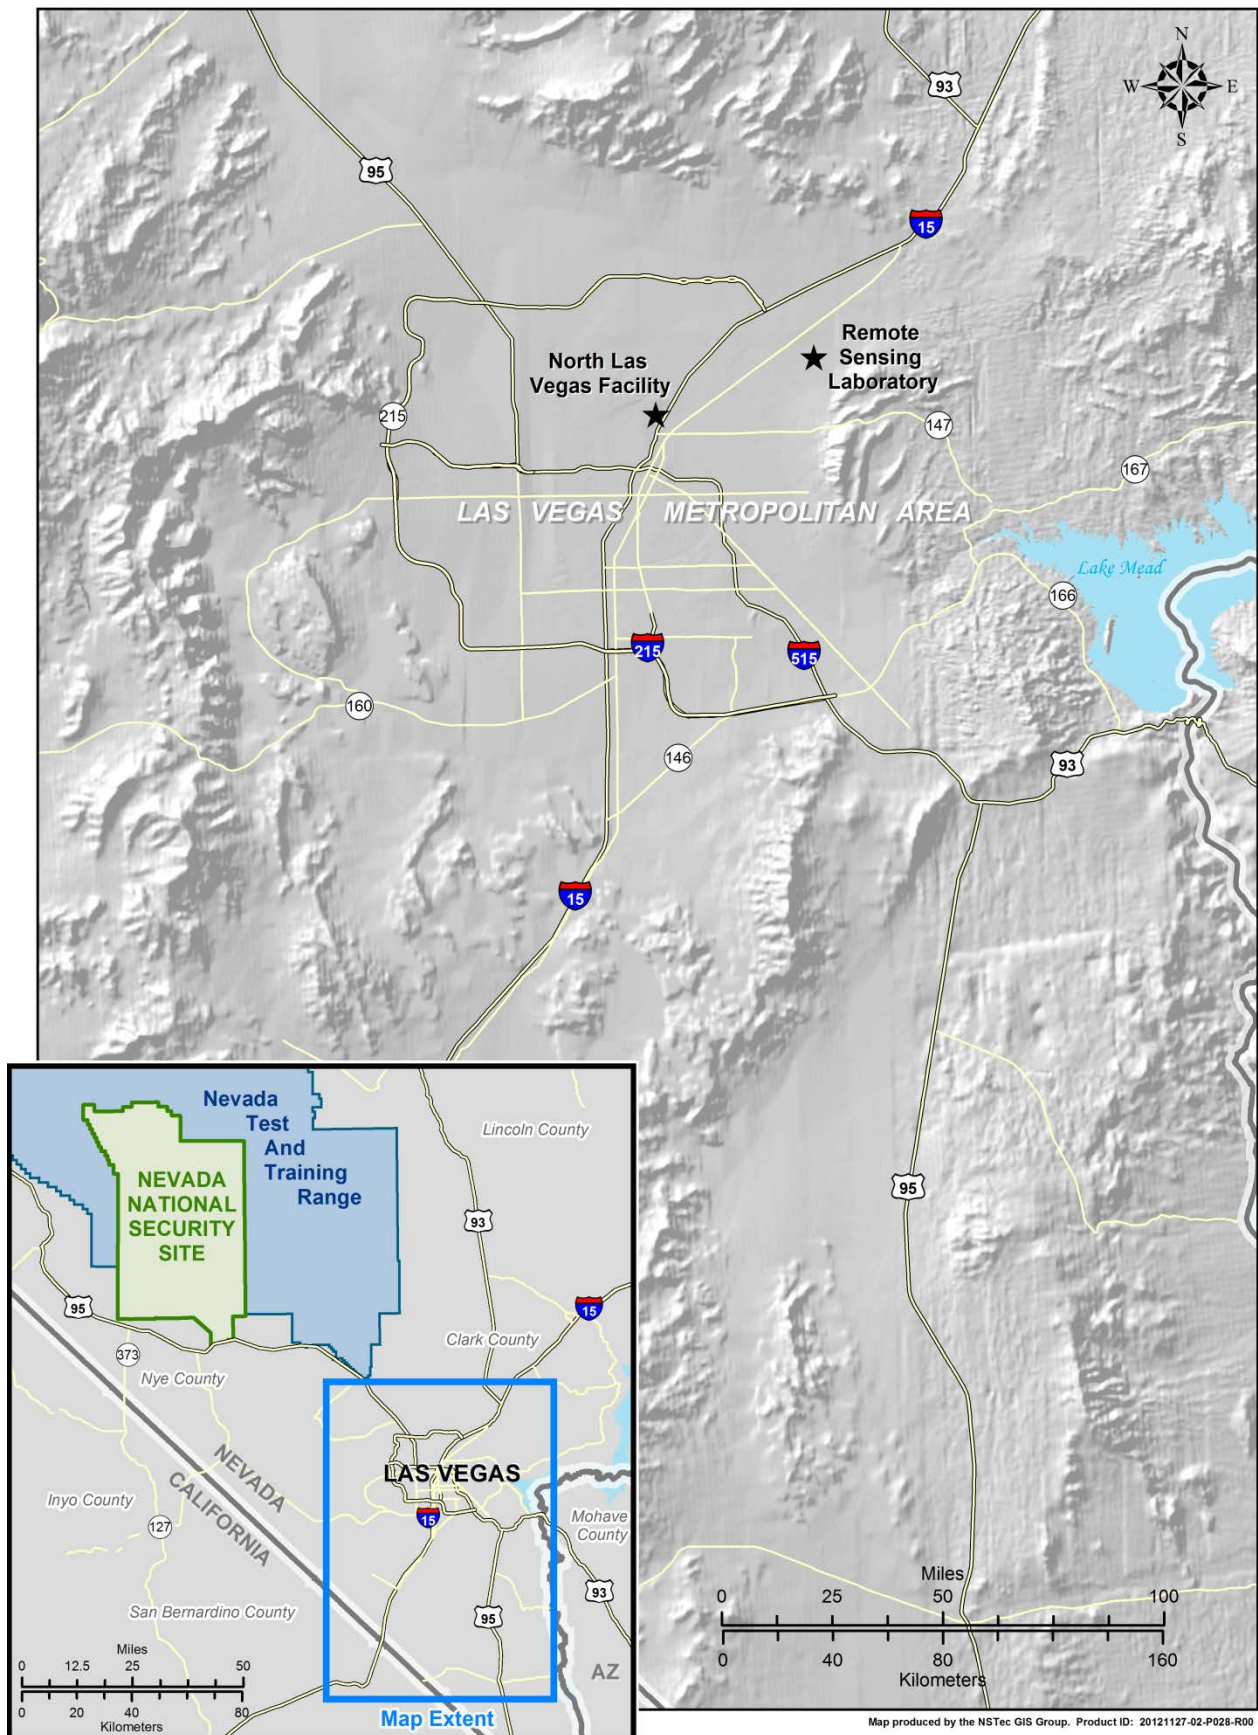

Figure A-1. Location of NNSS offsite facilities in Las Vegas and North Las Vegas

generators, emergency fire pump, emergency generator, and the cooling towers. There are other emission units at the NLVF for which the observation frequency is not specified. If emissions are observed, then U.S. Environmental Protection Agency (EPA) Method 9 opacity readings are recorded by a certified visible emissions evaluator. If visible emissions appear to exceed the limit, corrective actions must be taken to minimize emissions. In 2014, one NLVF Maintenance Engineer was recertified to conduct opacity readings. In 2014, observations were taken for the boilers, generators, the fire pump, and cooling towers; emissions were below the NAAQS opacity limit of 20%.

At NLVF, a verbal notification to the City of North Las Vegas (CNLV) Fire Department is required before each fire extinguisher training session. In 2014, one hot work live fire extinguisher training session was conducted at the NLVF. Quantities of criteria air pollutants produced by the open burns during training are not required to be calculated or reported.

A.1.2 Water Quality and Protection

Water used at the NLVF is supplied by the CNLV and meets or exceeds federal drinking water standards. Water quality permits issued to NNSA/NFO are for wastewaters discharged from the NLVF. NLVF wastewater permits in 2014 included a Class II Wastewater Control Permit from the CNLV for sewer discharges, and an NPDES permit issued by the Nevada Division of Environmental Protection (NDEP) for dewatering operations to control rising groundwater levels at the facility. Discharges of sewage and industrial wastewater from the NLVF must meet permit limits set by the CNLV. These limits support the permit limits for the Publicly Owned Treatment Works operated by the City of Las Vegas.

A.1.2.1 Wastewater Contribution Permit MSC-833

This new permit, issued in December 2013, specifies operations and maintenance practices and identifies substances which are prohibited from being discharged in NLVF wastewater. The permit requires that CNLV be notified when there are changes in discharge flow rates, deviations in operations or maintenance, spills, or other off-normal events. The permit does not require wastewater to be sampled and analyzed, as did previous permits. In 2014, no changes, deviations, spills, or other off-normal events requiring notification occurred at the NLVF.

A.1.2.2 National Pollution Discharge Elimination System Permit NV0023507

An NPDES permit (NV0023507) covers the dewatering operation conducted at the NLVF (see Section A.1.2.3). Dewatering wells (NLVF-13s, -15, -16, -17) pump groundwater into a 37,854-liter (L) (10,000-gallon [gal]) storage tank (Figure A-2). The permit allows for the discharge of water from the storage tank to groundwater via percolation, when used for landscape irrigation and dust suppression, and into the Las Vegas Wash via direct discharge into the CNLV storm water drainage system. The permit defines the discharge source via percolation as “Outfall 001” and via the storm water drainage system as “Outfall 002.” Water produced from the dewatering wells may also be used for purposes that do not require a groundwater discharge permit or an NPDES permit (e.g., evaporative cooling). Chemistry analyses are performed quarterly, annually, and biennially for water samples collected from the storage tank (Table A-2). The total quantities of groundwater produced and discharged and the results of groundwater chemistry analyses are reported quarterly to NDEP’s Bureau of Water Pollution Control.

In 2014, the four dewatering wells produced a total of about 10,221 L (2,700 gal) per day that were directed into the storage tank (Figure A-2). The average pumping rates varied from 2.5 liters per minute (Lpm) (0.65 gallons per minute [gpm]) at Well NLVF-17 to 0.79 Lpm (0.21 gpm) at Well NLVF-15. The average combined discharge from all four wells was about 302,833 L (80,000 gal) per month. Discharge rates did not exceed the NPDES permit limits (Table A-2). Quarterly and annual water samples from the holding tank had total petroleum hydrocarbons, total suspended solids, total dissolved solids, total inorganic nitrogen (as nitrogen [N]), pH, and tritium levels that were all below permit limits (Table A-2). Biennial water sampling for the presence of over 100 analytes (listed in Attachment A of the permit) was done in January 2013. Sampling for these analytes was not done in 2014.

Figure A-2. Location of dewatering and monitoring wells around Building A-1

Table A-2. NPDES Permit NV0023507 monitoring requirements and 2014 sampling results

Parameter	Monitoring Requirements		Permit Discharge Limits Daily Maximum	Sample Results			
	Sample Frequency	Sample Type		1 st Quarter	2 nd Quarter	3 rd Quarter	4 th Quarter
Daily Maximum Flow (MGD) ^(a)	Continuous	Flow Meter	0.0052	0.0021	0.0020	0.0029	0.0026
Total Petroleum Hydrocarbons (mg/L)	Annually (4 th Qtr)	Discrete	1.0	NS ^(b)	NS	NS	ND ^(c)
Total Suspended Solids (mg/L)	Quarterly	Discrete	135	ND	ND	ND	ND
Total Dissolved Solids (mg/L)	Quarterly	Discrete	1900	1260	1310	1850	1440
Total Inorganic Nitrogen as N (mg/L)	Quarterly	Discrete	20	1.20	1.20	1.22	1.17
pH (Standard Units)	Quarterly	Discrete	6.5–9.0	8.12	7.72	7.79	7.42
Tritium (picocuries per liter [pCi/L])	Annually (4 th Qtr)	Discrete	MR ^(d)	NS	NS	NS	ND

(a) MGD = million gallons per day

(b) NS = not required to be sampled that quarter

(c) ND = not detected; values were less than the laboratory detection limits

(d) MR = monitor and report; no specified daily maximum or 30-day average limit, just the requirement that there shall be no discharge of substances that would cause a violation of state water quality standards

A.1.2.3 Groundwater Control and Dewatering Operation

During 2014, the groundwater control and dewatering project at the NLVF continued efforts to reduce the intrusion of groundwater below Building A-1. The project has transitioned from initial groundwater investigations and characterization phases in 2002 to a long-term/permanent dewatering operational project. A review of the rising groundwater situation and past efforts to understand and remediate the problem is presented in previous reports (Bechtel Nevada [BN] 2003, 2004; NSTec 2006). Groundwater monitoring for this operation includes taking periodic water-level measurements at 24 accessible wells out of the 27 NLVF monitoring wells, taking continuous water-level measurements at the A-1 Basement Sump well, measuring the total volume of discharged groundwater, and conducting groundwater chemistry analyses in accordance with the NPDES permit. Groundwater data are assessed quarterly or as new data become available. This information is used to help characterize groundwater conditions, validate the conceptual hydrologic model, and evaluate the dewatering operation.

In 2014, about 302,833 L (80,000 gal) per month were pumped from the dewatering wells. Groundwater also continued to be pumped from the A-1 Basement Sump well (Figure A-2), totaling about 115,077 L (30,400 gal) per month in 2014. When the A-1 Basement Sump well pump is active, the water level directly beneath Building A-1 averages 24.1 centimeters (cm) (9.5 inches [in.]) below the basement floor, as measured in a monitoring tube installed in a nearby elevator shaft. This average water level is based on the daily measurements taken in 2014 and reflects a drop of about 45.7 cm (18 in.) in the local water table beneath Building A-1 since full-scale dewatering operations began in 2006. However, water levels in the 24 accessible NLVF monitoring wells, measured once a year in May, show a rising trend. In 2014, average monitoring well water levels were about 1.3 meters (4.2 feet) higher than levels obtained over the past 11 years. The dewatering efforts must continue to counter this rising groundwater trend.

A.1.2.4 Discharge of Groundwater from Building A-1 Sump Well

During 2001, the sump well was installed in the basement of Building A-1 and used in operations to remediate tritium contamination in the basement that occurred between 1994 and 1995 (BN 2000). The discharge water, which contained tritium, was disposed of at the NNSS. The sump well was turned off after the remedial operations were completed. However, beginning in early 2003, the sump well has been used to help control the encroaching water below Building A-1. The water contains some residual tritium, and it is segregated from the uncontaminated water from the dewatering operation. The amount of tritium in the sump well water has decreased over the last 11 years from about 1,900 pCi/L to 72 pCi/L (less than the average analytical minimum detection limit of 300 pCi/L) and less

than 1/200th of the Safe Drinking Water Act limit of 20,000 pCi/L). In 2014, a total of 1,381,861 L (365,049 gal) of water were pumped from the sump well and transported to the NNSS for disposal.

A.1.2.5 Oil Pollution Prevention

The NLVF has an SPCC Plan that was prepared in accordance with the Clean Water Act to minimize the potential discharge of petroleum products, animal fats and vegetable oils, and other non-petroleum oils and greases into waters of the U.S. (i.e., the Las Vegas Wash). The EPA requires SPCC Plans for non-transportation-related facilities having the potential to pollute waters of the U.S. and having an aggregate aboveground oil storage capacity of more than 4,997 L (1,320 gal). Oil storage facilities at the NLVF include 9 aboveground tanks, 18 transformers, 14 pieces of oil-filled machining equipment (e.g., lathes, elevators), and numerous 55-gal drums that are used to store new and used oils. These facilities/pieces of equipment are located within approved spill and storm water runoff containment structures. The SPCC specifies procedures for removing storm water from containment structures and identifies discharge countermeasures, disposal methods for recovered materials, and discharge reporting requirements.

In 2014, quarterly inspections of tanks, transformers, oil-filled equipment, and drums were conducted on March 25, June 19 and 24, September 24, and December 3 and 4. Throughout 2014, all NLVF employees who handle oil received their required annual spill prevention and management training. A small quantity (about 3.5 gallons) of oil leaked from a commercial vehicle driven onto the NLVF and was cleaned up. No spills occurred in 2014 that met regulatory agency reporting criteria.

A.1.3 Radiation Protection

A.1.3.1 National Emission Standards for Hazardous Air Pollutants (NESHAP)

In compliance with NESHAP of the Clean Air Act, the radionuclide air emissions from the NLVF and the resultant radiological dose to the public surrounding the facility were assessed. NESHAP establishes a dose limit for the general public to be no greater than 10 millirems per year (mrem/yr) from all radioactive air emissions. Building A-1's basement was contaminated with tritium in 1995 when a container of tritium foils was opened, emitting about 1 curie of tritium (U.S. Department of Energy, Nevada Operations Office 1996). Complete cleanup of the tritium was unsuccessful due to the tritium being absorbed into the building materials. This has resulted in a continuous but decreasing release of tritium into the basement air space, which is ventilated to the outdoors. Since 1995, a dose assessment has been performed every year for this building.

In 2014, no tritium was detected above its analytical minimum detection limit in groundwater pumped from the sump well in the basement of Building A-1 during dewatering operations. However, there is still an emission from tritium emanating from building materials in the building's basement. This tritium emission was determined by taking two air samples from the basement (on April 7–14 and September 8–15, 2014) in order to compute average tritium emissions. A calculated annual total of 1.72 millicuries were released from the basement air that was vented to the outside. Based on this emission rate, the 2014 calculated radiation dose to the nearest member of the general public from the NLVF was very low: 0.0000086 mrem/yr (NSTec 2015). The nearest public place is 100 meters (328 feet) northwest of Building A-1. This annual public dose is well below the regulatory limit of 10 mrem/yr and continues to decrease at a rate of about one-half every 4.75 years (NSTec 2015).

A.1.3.2 DOE O 458.1

U.S. Department of Energy (DOE) Order DOE O 458.1, "Radiation Protection of the Public and the Environment," specifies that the radiological dose to a member of the public from radiation from all pathways must not exceed 100 mrem/yr as a result of DOE activities. This dose limit does not include the dose contribution from natural background radiation. The Atlas A-1 Source Range Laboratory and the Building C-3 High Intensity Source Building are two NLVF facilities that use radioactive sources or where radiation-producing operations are conducted that have the potential to expose the general population or non-project personnel to direct radiation. Direct radiation monitoring is conducted using thermoluminescent dosimeters (TLDs) to monitor external gamma radiation exposure near the boundaries of these facilities. The methods of TLD use and data analyses are described in Chapter 6 of this report.

In 2014, radiation exposure was measured at two locations along perimeter fences for Buildings A-1 and C-3 and at one control location along the west fence of Building C-1 (Figure A-2). Annual exposure rates estimated from measurements at those locations are summarized in Table A-3. The radiation exposure in air measured by the TLDs is in the unit of milliroentgens per year (mR/yr), which is considered equivalent to the unit of mrem/yr for tissue. These exposures include contributions from background radiation and are similar to the TLD measurement of 109 mR/yr for total annual exposure reported by the Desert Research Institute from their Las Vegas air monitoring station (see Section 7.1.4, Table 7-3). The NLVF TLD results indicate that facility activities do not contribute a radiological dose to the surrounding public that can be distinguished from the dose due to background radiation.

Table A-3. Results of 2014 direct radiation exposure monitoring at the NLVF

Location	Number of Samples	Mean	Gamma Exposure (mR/yr)		
			Median	Minimum	Maximum
West Fence of Building C-1 (Control)	4	97	99	90	100
North Fence of Building A-1	4	65	65	61	69
North Fence of Building C-3	4	65	64	61	69

A.1.4 Hazardous Waste Management

Hazardous wastes (HWs) generated at the NLVF include such items as non-empty aerosol cans, lead debris, and oily rags. HWs are stored temporarily in satellite accumulation areas until they are direct-shipped to approved disposal facilities. The NLVF is a Conditionally Exempt Small Quantity Generator; therefore, no HW permit is required by the State of Nevada. However, once a year, the Southern Nevada Health District (SNHD) conducts an onsite audit to validate proper handling and storage. SNHD personnel conducted the annual audit on July 31, 2014, and found existing HW procedures acceptable.

A.1.5 Hazardous Materials Control and Management

In 2014, the chemical inventory at the NLVF was updated and submitted to the State in the Nevada Combined Agency (NCA) Report on February 13, 2015. The inventory data were submitted in accordance with the requirements of the Hazardous Materials Permit 26779 (see Section 2.6, Emergency Planning and Community Right-to-Know Act, for a description of the content, purpose, and federal regulatory driver behind the NCA Report). No accidental or unplanned release of an extremely hazardous substance (EHS) occurred at the NLVF in 2014. Also, the quantities of toxic chemicals kept at the NLVF that are used annually did not exceed the specified reporting thresholds (see Section 2.6 concerning Toxic Chemical Release Inventory, Form R).

A.2 Remote Sensing Laboratory–Nellis

RSL-Nellis is approximately 13.7 kilometers (km) (8.5 miles [mi]) northeast of the Las Vegas city center, and approximately 11.3 km (7 mi) northeast of the NLVF. It occupies six facilities on approximately 14 secured hectares (35 acres) at the Nellis Air Force Base. The six NNSA/NFO facilities were constructed on property owned by the U.S. Air Force (USAF). There is a Memorandum of Agreement between the USAF and NNSA/NFO whereby the land belongs to the USAF but is under lease to the NNSA/NFO for 25 years (as of 1989) with an option for a 25-year extension. The facilities are owned by NNSA/NFO. RSL-Nellis provides emergency response resources for weapons-of-mass-destruction incidents. The laboratory also designs and conducts field tests of counterterrorism/intelligence technologies, and has the capability to assess environmental and facility conditions using complex radiation measurements and multi-spectral imaging technologies.

Environmental compliance and monitoring activities at RSL-Nellis in 2014 included maintenance of an air quality permit, a wastewater discharge permit, a hazardous materials permit, and a waste management permit (see Chapter 2, Table 2-13 for a list of all NNSA/NFO permits). Sealed radiation sources are used for calibration at RSL-Nellis, but the public has no access to any area that may have elevated gamma radiation emitted by the sources. Therefore, no environmental TLD monitoring is conducted. However, dosimetry monitoring is performed to ensure protection of personnel who work within the facility.

A.2.1 Air Quality and Protection

Sources of air pollutants at RSL-Nellis are regulated by the Synthetic Minor Source Permit 348 for the emission of criteria pollutants and HAPs issued by the Clark County DAQ. The regulated sources of emissions at RSL-Nellis include an aluminum sander, an abrasive blaster, spray paint booth, diesel generators, a fire pump, cooling towers, and boilers. In 2014, two emergency generators were added to the air permit and one temporary experimental operation was performed for a period of 24 days, using two generators and one nitrogen generating cart. The 2014 emissions inventory of criteria air pollutants and HAPs was submitted to the DAQ on March 12, 2015, and is shown in Table A-4.

Clark County air regulations specify that the opacity from any emission unit may not exceed the Clean Air Act NAAQS opacity limit of 20% for more than 6 consecutive minutes. The RSL-Nellis air permit requires that equipment be observed each day it is operated. If visible emissions are observed, then EPA Method 9 opacity readings are recorded by a certified visible emissions evaluator. If visible emissions appear to exceed the limit, corrective actions must be taken to minimize emissions. In 2014, one RSL-Nellis Maintenance Engineer was recertified to conduct opacity readings. Readings were taken for generators, a paint booth, aluminum sander, and sand blaster. Emissions for all equipment were well below the Clean Air Act NAAQS opacity limit of 20%.

Table A-4. Summary of air emissions for RSL-Nellis in 2014

Parameter	Criteria Pollutant (Tons/yr) ^(a)						
	PM10 ^(b)	PM2.5 ^(c)	NO _x	CO	SO ₂	VOC	HAPs (Tons/yr)
PTE ^(d)	1.37	0.95	14.23	4.22	0.85	1.65	0.41
Actual ^(e)	0.60	0.47	8.97	2.34	0.36	0.52	0.03
Total Emissions = 13.29 Actual, 23.68 PTE							

(a) 1 ton equals 0.91 metric tons

(b) Particulate matter equal to or less than 10 microns in diameter

(c) Particulate matter equal to or less than 2.5 microns in diameter

(d) Potential to emit: The quantity of criteria air pollutant that facilities/pieces of equipment would emit annually if they were operated for the maximum number of hours at the maximum production rate specified in the air permit

(e) Emissions based on calculations using actual hours of operation for each piece of equipment

Twice a year, the operating hours and throughputs for each permitted piece of equipment must be submitted to Clark County. These semi-annual reports were submitted on July 16, 2014 for the period January through June and on January 29, 2015 for the period July through December.

A.2.2 Water Quality and Protection

Water used at RSL-Nellis is supplied by the CNLV and meets or exceeds federal drinking water standards. The previous Wastewater Contribution Permit CCWRD-080, issued by the Clark County Water Reclamation District (CCWRD) for wastewaters discharged from RSL-Nellis, expired in 2013. During the permit renewal process in 2013, CCWRD determined that a discharge permit would no longer be necessary for RSL-Nellis since no industrial wastewaters were being discharged. Wastewater quality monitoring is no longer required, only the annual submission of a Zero Discharge Form. As required, a Zero Discharge Form for 2014 was submitted to CCWRD on January 13, 2015. There were no regulatory inspections of RSL-Nellis by the CCWRD in 2014 and no findings or corrective actions for the facility were identified by internal assessments.

A.2.2.1 Oil Pollution Prevention

An SPCC Plan is in place for RSL-Nellis. Similar to the NLVF (see Section A.1.3), the SPCC Plan is required because the facility has an aggregate aboveground oil storage capacity of more than 4,997 L (1,320 gal) and spills could potentially enter the Las Vegas Wash. Oil storage facilities at RSL-Nellis include nine aboveground tanks, four transformers, and two pieces of oil-filled machining equipment (e.g., elevators). These facilities and pieces of equipment are located within approved spill and storm water runoff containment structures. The SPCC specifies procedures for removing storm water from containment structures and identifies discharge countermeasures, disposal methods for recovered materials, and discharge reporting requirements.

In 2014, quarterly inspections of tanks, transformers, and oil-filled equipment were conducted on January 30, April 22, July 31, and October 29. Throughout 2014, all RSL-Nellis employees who handle oil received their required annual spill prevention and management training. A small quantity (about 0.25 gallons) of diesel fuel leaked from a dispensing nozzle during fueling of a generator and was cleaned up. No spills occurred in 2014 that met regulatory agency reporting criteria.

A.2.3 *Underground Storage Tank (UST) Management*

The SNHD has oversight authority of USTs in Clark County. The UST program at RSL-Nellis consists of three fully regulated tanks (one for unleaded gasoline, one for diesel fuel, and one for used oil), one deferred tank (in accordance with Title 40 Code of Federal Regulations Part 280.10[d]) for emergency power generation, and three excluded tanks. The active tanks are inspected annually by SNHD. In 2014, SNHD inspected the fully regulated and deferred USTs at RSL-Nellis. No deficiencies were noted, however, SNHD recommended that the ball floats be removed from two regulated tanks. When flapper valves, newer equipment also used to prevent tank overfill, were installed in the tanks in 2010, the ball floats had been left in place. Updated information received from SNHD recommended that only one type of overfill protection be used, therefore the ball floats were removed as a best management practice.

A.2.4 *Hazardous Materials Control and Management*

In 2014, the chemical inventory at RSL-Nellis was updated and submitted to the State in the NCA Report on February 13, 2015, in accordance with the requirements of the Hazardous Materials Permit 26781 (see Section 2.6 of this report for a description of the content, purpose, and federal regulatory driver behind the NCA Report). No accidental or unplanned release of an EHS occurred at RSL-Nellis in 2014. Also, no annual usage quantities of toxic chemicals kept at RSL-Nellis exceeded specified thresholds (see Section 2.6 concerning Toxic Chemical Release Inventory, Form R).

THIS PAGE INTENTIONALLY LEFT BLANK

Appendix B: Glossary of Terms

- A** **Absorbed radiation dose:** the amount of energy imparted to matter by ionizing radiation per unit mass of irradiated material, in which the absorbed dose is expressed in units of rad or gray (1 rad equals 0.01 gray).
- Accuracy:** the closeness of the result of a measurement to the true value of the quantity measured.
- Action level:** defined by regulatory agencies as the level of pollutant(s) that, if exceeded, requires regulatory action.
- Alluvium:** a sediment deposited by flowing water.
- Alpha particle:** a positively charged particle emitted from the nucleus of an atom, having mass and charge equal to those of a helium nucleus (two protons and two neutrons), usually emitted by transuranic elements.
- Analyte:** the specific component measured in a chemical analysis.
- Aquifer:** a saturated layer of rock or soil below the ground surface that can supply usable quantities of groundwater to wells and springs, and be a source of water for domestic, agricultural, and industrial uses.
- Area 5 Radioactive Waste Management Complex (RWMC):** the complex in Area 5 of the Nevada National Security Site at which low-level waste (LLW) and mixed low-level waste (MLLW) may be received, examined, packaged, stored, or disposed. Limited quantities of onsite-generated transuranic waste (TRU) are also stored temporarily at the RWMC. The RWMC is composed of the Area 5 Radioactive Waste Management Site (RWMS) and the Waste Examination Facility (WEF) and supporting administrative buildings, parking areas, and utilities. The operational units of the Area 5 RWMS include active, inactive, and closed LLW and MLLW cells and a Real Time Radiography Building. The operational units of the WEF include the TRU Pad, TRU Pad Cover Building, TRU Loading Operations Area, WEF Yard, WEF Drum Holding Pad, Sprung Instant Structure, and the Visual Examination and Repackaging Building.
- Atom:** the smallest particle of an element capable of entering into a chemical reaction.
- B** **Background:** as used in this report, background is the term for the amounts of chemical constituents or radioactivity in the environment that are not caused by Nevada National Security Site operations. In the broader context outside this report, background radiation refers to radiation arising from natural sources always present in the environment, including solar and cosmic radiation from outer space and naturally radioactive elements in the atmosphere, the ground, building materials, and the human body.
- Becquerel (Bq):** the International System of Units unit of activity of a radionuclide, equal to the activity of a radionuclide having one spontaneous nuclear transition per second.
- Beta particle:** a negatively charged particle emitted from the nucleus of an atom, having charge, mass, and other properties of an electron, emitted from fission products such as cesium-137.
- Biological oxygen demand (BOD):** a measure of the amount of dissolved oxygen that microorganisms need to break down organic matter in water; used as an indicator of water quality.
- C** **CAP88-PC:** a computer code required by the U.S. Environmental Protection Agency for modeling air emissions of radionuclides.
- Code of Federal Regulations (CFR):** a codification of all regulations promulgated by federal government agencies.
- Collective population dose:** the sum of the total effective dose equivalents of all individuals within a defined population. The unit of collective population dose is person-rem or person-sievert. Collective population dose may also be referred to as “collective effective dose equivalent” or simply “population dose.”

Committed dose equivalent: the dose equivalent to a tissue or organ over a 50-year period after an intake of a radionuclide into the body. Committed dose equivalent is expressed in units of rem or sievert.

Committed effective dose equivalent (CEDE): the sum of the committed dose equivalents to various tissues in the body, each multiplied by an appropriate weighting factor representing the relative vulnerability of different parts of the body to radiation. Committed effective dose equivalent is expressed in units of rem or sievert.

Community water system: as defined in Nevada Revised Statute 445A.808, it is a public water system that has at least 15 service connections used by year-round residents of the area served by the system; or regularly serves at least 25 year-round residents of the area served by the system.

Compliance Level (CL): the Clean Air Act National Emission Standards for Hazardous Air Pollutants Concentration Level for Environmental Compliance. The CL value represents the annual average concentration that would result in a dose of 10 millirem per year, which is the federal dose limit to the public from all radioactive air emissions.

Confining unit: a geologic unit of relatively low permeability that impedes the vertical movement of groundwater.

Cool roof: a low-sloped roof (pitch less than or equal to 2:12) that is designed and installed with a minimum 3-year aged solar reflectance of 0.55 and a minimum 3-year aged thermal emittance of 0.75, or with a minimum 3-year aged solar reflectance index (SRI) of 64. Cool steep-sloped roofs (pitch exceeding 2:12) have a 3-year SRI of 29 or higher.

Cosmic radiation: radiation with very high energies originating outside the earth's atmosphere; it is one source contributing to natural background radiation.

Criteria pollutants: those air pollutants designated by the U.S. Environmental Protection Agency as potentially harmful and for which National Ambient Air Quality Standards under the Clean Air Act have been established to protect the public health and welfare. These pollutants include sulfur dioxide (SO₂), nitrogen oxides (NO_x), carbon monoxide (CO), ozone, lead, and particulate matter equal to or less than 10 microns in diameter (PM₁₀). The State of Nevada, through an air quality permit, establishes emission limits on the Nevada National Security Site for SO₂, NO_x, CO, PM₁₀, and volatile organic compounds (VOCs). Ozone is not regulated by the permit as an emission, as it is formed in part from NO_x and VOCs. Lead is considered a hazardous air pollutant (HAP) as well as a criteria pollutant, and lead emissions on the Nevada National Security Site are reported as part of the total HAP emissions. Lead emissions above a specified threshold are also reported under Section 313 of the Emergency Planning and Community Right-to-Know Act.

Critical Level (L_C): the counts of radioactivity (or concentration level of a radionuclide) in a sample that must be exceeded before there is a specified level of confidence (typically 95 or 99 percent) that the sample contains radioactive material above the background; called the Critical Level (L_C) or the decision level.

Curie (Ci): a unit of measurement of radioactivity, defined as the amount of radioactive material in which the decay rate is 3.7×10^{10} (37 billion) disintegrations per second; one Ci is approximately equal to the decay rate of one gram of pure radium.

D Daughter nuclide: a nuclide formed by the radioactive decay of another nuclide, which is called the parent.

Decision level: the counts of radioactivity (or concentration level of a radionuclide) in a sample that must be exceeded before there is a specified level of confidence (typically 95 or 99 percent) that the sample contains radioactive material above the background; also known as the Critical Level (L_C).

Depleted uranium: uranium having a lower proportion of the isotope ²³⁵U than is found in naturally occurring uranium. The masses of the three uranium isotopes with atomic weights 238, 235, and 234 occur in depleted uranium in the weight-percentages 99.8, 0.2, and 5×10^{-4} , respectively.

Derived Concentration Guide (DCG): previously published standard in U.S. Department of Energy (DOE) Order DOE O 5400.5 from 1993, which was the concentration of a given radionuclides in water or air that could be continuously consumed or inhaled for 1 year and not exceed the DOE primary radiation dose limit to the public of 100 millirem per year effective dose equivalent. DCGs were replaced in 2011 by Derived Concentration Standards (DCSs).

Derived Concentration Standard (DCS): concentration of a given radionuclide in either water or air that results in a member of the public receiving 100 millirem (1 millisievert) effective dose following continuous exposure for one year via each of the following pathways: ingestion of water, submersion in air, and inhalation. They replace the DCGs previously published by the U.S. Department of Energy (DOE) in 1993 in DOE Order DOE O 5400.5. Since 1993, the radiation protection framework on which DCSs are based has evolved with more sophisticated biokinetic and dosimetric information provided by the International Commission on Radiological Protection (ICRP), thus enabling consideration of age and gender. DOE-STD-1196-2011 establishes DCS values that reflect the current state of knowledge and practice in radiation protection. These DCSs are based on age-specific effective dose coefficients, revised gender specific physiological parameters for the Reference Man (ICRP 2002), and the latest information on the energies and intensities of radiation emitted by radionuclides (ICRP 2008).

Dose: the energy imparted to matter by ionizing radiation; the unit of absorbed dose is the rad, equal to 0.01 joules per kilogram for irradiated material in any medium.

Dose equivalent: the product of absorbed dose in rad (or gray) in tissue and a quality factor representing the relative damage caused to living tissue by different kinds of radiation, and perhaps other modifying factors representing the distribution of radiation, etc., expressed in units of rem or sievert.

Dosimeter: a portable detection device for measuring the total accumulated exposure to ionizing radiation.

Dosimetry: the theory and application of the principles and techniques of measuring and recording radiation doses.

E Effective dose equivalent (EDE): an estimate of the total risk of potential effects from radiation exposure; it is the summation of the products of the dose equivalent and weighting factor for each tissue. The weighting factor is the decimal fraction of the risk arising from irradiation of a selected tissue to the total risk when the whole body is irradiated uniformly to the same dose equivalent. These factors permit dose equivalents from non-uniform exposure of the body to be expressed in terms of an EDE that is numerically equal to the dose from a uniform exposure of the whole body that entails the same risk as the internal exposure. The EDE includes the committed effective dose equivalent from internal deposition of radionuclides and the EDE caused by penetrating radiation from sources external to the body, and is expressed in units of rem or sievert.

Effluent: used in this report to refer to a liquid discharged to the environment.

Emission: used in this report to refer to a vapor, gas, airborne particulate, or to radiation discharged to the environment via the air.

Energy Performance Contract: also known as an Energy Savings Performance Contract (ESPC) and a Utility Energy Service Contract (UESC), it is an alternative financing mechanism authorized by the U.S. Congress designed to accelerate investment in cost effective energy conservation measures in existing federal buildings. ESPCs allow federal agencies to accomplish energy savings projects without up-front capital costs and without special Congressional appropriations. The contract is a partnership between a federal agency and an energy service company (ESCO). The ESCO conducts a comprehensive energy audit for the federal facility and identifies improvements to save energy. In consultation with the federal agency, the ESCO designs and constructs a project that meets the agency's needs and arranges the necessary financing. The ESCO guarantees that the improvements will generate energy cost savings sufficient to pay for the project over the term of the contract. After the contract ends, all additional cost savings accrue to the agency. The savings must be guaranteed and the federal agencies may enter into a multiyear contract for a period not to exceed 25 years.

ESPC ENABLE: a program provided through DOE’s Federal Energy Management Program (FEMP) that provides a standardized and streamlined process for small, federal facilities to install targeted, energy conservation measures (ECMs) in 6 months or less. Projects are administered through the General Services Administration (GSA) Federal Supply Schedule 84, Special Identification Number (SIN) 246-53 using a set of pre-established procurement and technical tools. The program allows sites an opportunity to implement specific ECMs pertaining to lighting, water, simple heating, ventilation, and air conditioning (HVAC) controls, HVAC system replacement, and solar photovoltaics.

F Federal facility: a facility that is owned or operated by the federal government, subject to the same requirements as other responsible parties when placed on the Superfund National Priorities List.

Federal Register: a document published daily by the federal government containing notification of government agency actions, including notification of U.S. Environmental Protection Agency and U.S. Department of Energy decisions concerning permit applications and rule-making.

Fiscal year: the U.S. Department of Energy, National Nuclear Security Administration Nevada Field Office’s fiscal year is from October 1 through September 30.

G Gamma ray: high-energy, short-wavelength, electromagnetic radiation emitted from the nucleus of an atom, frequently accompanying the emission of alpha or beta particles.

Gray (Gy): the International System of Units unit of measure for absorbed dose; the quantity of energy imparted by ionizing radiation to a unit mass of matter, such as tissue. One gray equals 100 rads, or 1 joule per kilogram.

Gross alpha: the measure of radioactivity caused by all radionuclides present in a sample that emit alpha particles. Gross alpha measurements reflect alpha activity from all sources, including those that occur naturally. Gross measurements are used as a method to screen samples for relative levels of radioactivity.

Gross beta: the measure of radioactivity caused by all radionuclides present in a sample that emit beta particles. Gross beta measurements reflect beta activity from all sources, including those that occur naturally. Gross measurements are used as a method to screen samples for relative levels of radioactivity.

H Half-life: the time required for one-half of the radioactive atoms in a given amount of material to decay; for example, after one half-life, half of the atoms will have decayed; after two half-lives, three-fourths; after three half-lives, seven-eighths; and so on, exponentially.

Hazardous air pollutants (HAPs): Toxic air pollutants that are known or suspected to cause cancer or other serious health effects, such as reproductive effects or birth defects, or adverse environmental effects. The U.S. Environmental Protection Agency has set emission standards for 22 of the 187 designated HAPs. Examples of toxic air pollutants include benzene, which is found in gasoline; perchloroethylene, which is emitted from some dry cleaning facilities; and methylene chloride, which is used as a solvent and paint stripper by a number of industries. Examples of other listed air toxics include dioxin, asbestos, toluene, and metals such as cadmium, mercury, chromium, and lead compounds.

Hazardous waste: hazardous wastes exhibit any of the following characteristics: ignitability, corrosivity, reactivity, or Extraction Procedure toxicity (yielding excessive levels of toxic constituents in a leaching test), but other wastes that do not necessarily exhibit these characteristics have been determined to be hazardous by the U.S. Environmental Protection Agency (EPA). Although the legal definition of hazardous waste is complex, according to the EPA, the term generally refers to any waste that, if managed improperly, could pose a threat to human health and the environment.

High-efficiency particulate air (HEPA) filter: a disposable, extended-media, dry-type filter used to capture particulates in an air stream; HEPA collection efficiencies are at least 99.97 percent for 0.3-micrometer diameter particles.

Hydrology: the science dealing with the properties, distribution, and circulation of natural water systems.

I Inorganic compounds: compounds that either do not contain carbon or do not contain hydrogen along with carbon, including metals, salts, various carbon oxides (e.g., carbon monoxide and carbon dioxide), and cyanide.

Instrument detection limit (IDL): the lowest concentration that can be detected by an instrument without correction for the effects of sample matrix or method-specific parameters such as sample preparation. IDLs are explicitly determined and generally defined as three times the standard deviation of the mean noise level. This represents 99 percent confidence that the signal is not random noise.

Interim status: a legal classification allowing hazardous waste incinerators or other hazardous waste management facilities to operate while the U.S. Environmental Protection Agency considers their permit applications, provided that they were under construction or in operation by November 19, 1980, and can meet other interim status requirements.

International System of Units (SI): an international system of physical units that includes meter (length), kilogram (mass), kelvin (temperature), becquerel (radioactivity), gray (radioactive dose), and sievert (dose equivalent). The abbreviation, SI, comes from the French term *Système International d'Unités*.

Isotopes: forms of an element having the same number of protons in their nuclei, but differing numbers of neutrons.

L L_C: see Critical Level (L_C).

Less than detection limits: a phrase indicating that a chemical constituent or radionuclide was either not present in a sample, or is present in such a small concentration that it cannot be measured as significantly different from zero by a laboratory's analytical procedure and, therefore, is not identified at the lowest level of sensitivity.

Low-level waste (LLW): defined by U.S. Department of Energy Manual DOE M 435.1-1, "Radioactive Waste Management Manual," as radioactive waste that is not high-level radioactive waste, spent nuclear fuel, transuranic waste, byproduct material (as defined in section 11e.(2) of the Atomic Energy Act of 1954, as amended), or naturally occurring radioactive material.

Lower limit of detection: the smallest concentration or amount of analyte that can be detected in a sample at a 95-percent confidence level; also known as minimum detectable concentration.

Lysimeter: an instrument for measuring the water percolating through soils and determining the dissolved materials.

M Maximally exposed individual (MEI): a hypothetical member of the public at a fixed location who, over an entire year, receives the maximum effective dose equivalent (summed over all pathways) from a given source of radionuclide releases to air. Generally, the MEI is different for each source at a site.

Maximum contaminant level (MCL): the highest level of a contaminant in drinking water that is allowed by U.S. Environmental Protection Agency regulation.

Minimum detectable concentration (MDC): also known as the lower limit of detection, the smallest amount of radioactive material in a sample that can be quantitatively distinguished from background radiation in the sample with 95 percent confidence.

Metric units: metric units, U.S. customary units, and their respective equivalents are shown in Table 1-6. Except for temperature, for which specific equations apply, U.S. customary units can be determined from metric units by multiplying the metric units by the U.S. customary equivalent. Similarly, metric units can be determined from U.S. customary equivalent units by multiplying the U.S. customary units by the metric equivalent.

Mixed low-level waste (MLLW): waste containing both radioactive and hazardous components.

N National Emission Standards for Hazardous Air Pollutants (NESHAP): standards found in the Clean Air Act that set limits for hazardous air pollutants.

National Pollutant Discharge Elimination System (NPDES): a federal regulation under the Clean Water Act that requires permits for discharges into surface waterways.

Non-community water system: as defined in Nevada Revised Statute 445A.828, it is a public water system that is not a community water system. Private water system: on the NNSS, a water system that is not a public water system and is not regulated under State of Nevada permits.

Nuclide: any species of atom that exists for a measurable length of time. A nuclide can be distinguished by its atomic mass, atomic number, and energy state.

P Part B Permit: the second, narrative section submitted by generators in the Resource Conservation and Recovery Act permitting process that covers in detail the procedures followed at a facility to protect human health and the environment.

Parts per million (ppm): a unit of measure for the concentration of a substance in its surrounding medium; for example, one million grams of water containing one gram of salt has a salt concentration of 1 ppm.

Perched aquifer: an aquifer that is separated from another water-bearing stratum by an impermeable layer.

pH: a measure of hydrogen ion concentration in an aqueous solution. Acidic solutions have a pH from 0 to 7, basic solutions have a pH greater than 7, and neutral solutions have a pH of 7.

PM10: a fine particulate matter with an aerodynamic diameter equal to or less than 10 microns.

Point source: any confined and discrete conveyance (e.g., pipe, ditch, well, or stack).

Private water system: a water system that is not a public water system, as defined in Nevada Revised Statute 445A.235, and is not regulated under State of Nevada permits.

Public water system (PWS): as defined in Nevada Revised Statute 445A.235, it is a system, regardless of ownership, that provides the public with water for human consumption through pipes or other constructed conveyances, if the system has 15 or more service connections, as defined in NRS 445A.843, or regularly serves 25 or more persons. The three PWSs on the NNSS are permitted by the State of Nevada as non-community water systems.

Q Quality assurance (QA): a system of activities whose purpose is to provide the assurance that standards of quality are attained with a stated level of confidence.

Quality control (QC): procedures used to verify that prescribed standards of performance are attained.

Quality factor: the factor by which the absorbed dose (rad) is multiplied to obtain a quantity that expresses (on a common scale for all ionizing radiation) the biological damage to exposed persons, usually used because some types of radiation, such as alpha particles, are biologically more damaging than others. Quality factors for alpha, beta, and gamma radiation are in the ratio 20:1:1.

R Rad: the unit of absorbed dose and the quantity of energy imparted by ionizing radiation to a unit mass of matter such as tissue; equal to 0.01 joule per kilogram, or 0.01 gray.

Radioactive decay: the spontaneous transformation of one radionuclide into a different nuclide (which may or may not be radioactive), or de-excitation to a lower energy state of the nucleus by emission of nuclear radiation, primarily alpha or beta particles, or gamma rays (photons).

Radioactivity: the spontaneous emission of nuclear radiation, generally alpha or beta particles, or gamma rays, from the nucleus of an unstable isotope.

Radionuclide: an unstable nuclide. See nuclide and radioactivity.

Rem: a unit of radiation dose equivalent and effective dose equivalent describing the effectiveness of a type of radiation to produce biological effects; coined from the phrase “roentgen equivalent man.” The product of the absorbed dose (rad), a quality factor (Q), a distribution factor, and other necessary modifying factors. One rem equals 0.01 sievert.

Roentgen (R): a unit of measurement used to express radiation exposure in terms of the amount of ionization produced in a volume of air.

S Sanitary waste: most simply, waste generated by routine operations that is not regulated as hazardous or radioactive by state or federal agencies.

Saturated zone: a subsurface zone below which all rock pore-space is filled with water; also called the phreatic zone.

Sievert (Sv): the International System of Units unit of radiation dose equivalent and effective dose equivalent, that is the product of the absorbed dose (gray), quality factor, distribution factor, and other necessary modifying factors; 1 Sv equals 100 rem.

Source term: the amount of a specific pollutant emitted or discharged to a particular medium, such as the air or water, from a particular source.

Specific conductance: the measure of the ability of a material to conduct electricity; also called conductivity.

Subcritical experiment: an experiment using high explosives and nuclear weapon materials (including special nuclear materials like plutonium) to gain data used to maintain the nuclear stockpile without conducting nuclear explosions banned by the Comprehensive Nuclear Test Ban Treaty.

T Thermoluminescent dosimeter (TLD): a device used to measure external beta or gamma radiation levels, and which contains a material that, after exposure to beta or gamma radiation, emits light when processed and heated.

Total dissolved solids (TDS): the total mass of particulate matter per unit volume that is dissolved in water and that can pass through a very fine filter.

Total effective dose equivalent (TEDE): The sum of the external exposures and the committed effective dose equivalent (CEDE) for internal exposures.

Total organic carbon (TOC): the sum of the organic material present in a sample.

Total organic halides (TOX): the sum of the organic halides present in a sample.

Total suspended solids (TSS): the total mass of particulate matter per unit volume suspended in water and wastewater discharges that is large enough to be collected by a very fine filter.

Transpiration: a process by which water is transferred from the soil to the air by plants that take the water up through their roots and release it through their leaves and other aboveground tissue.

Tritium: a radioactive form of hydrogen that is produced naturally in the upper atmosphere when cosmic rays strike nitrogen molecules in the air. Although tritium can be a gas, its most common form is in water, because, like non-radioactive hydrogen, tritium reacts with oxygen to form water. Tritium replaces one of the stable hydrogens in the water molecule, H₂O, and is called tritiated water (HTO). Like H₂O, tritiated water is colorless and odorless. Naturally-occurring tritium is found in very small or trace amounts in the environment

as HTO, which easily disperses in the atmosphere, water bodies, soil, and rock. Tritium is also produced during nuclear weapons explosions, as a by-product in nuclear reactors producing electricity, and in special production reactors, where the isotope lithium-6 is bombarded to produce tritium. In the mid-1950s and early 1960s, tritium was widely dispersed during the above-ground testing of nuclear weapons. The quantity of tritium in the atmosphere from weapons testing peaked in 1963 and has been decreasing ever since. Tritium is a contaminant of groundwater in select areas of the NNSS as a result of historical underground nuclear testing and is the contaminant of concern being monitored in NNSS groundwater samples. Tritium decays at a half-life of 12.3 years by emitting a low-energy beta particle. In 1976, EPA established a dose-based drinking water standard of 4 mrem per year and set a maximum contaminant level for drinking water of 20,000 picocuries per liter (pCi/L) for tritium, the level assumed to yield a dose of 4 mrem per year. One year of drinking water with this amount of contamination would produce approximately the same dose of radiation you would get during a single commercial flight between Los Angeles and New York City.

Transuranic (TRU) waste: material contaminated with alpha-emitting transuranium nuclides that have an atomic number greater than 92 (e.g., ²³⁹Pu), half-lives longer than 20 years, and are present in concentrations greater than 100 nanocuries per gram of waste.

U Uncertainty: the parameter associated with a sample measurement that characterizes the range of the measurement that could reasonably be attributed to the sample. Used in this report, the uncertainty value is established at ± 2 standard deviations.

Unsaturated zone: that portion of the subsurface in which the pores are only partially filled with water and the direction of water flow is vertical; also referred to as the vadose zone.

V Vadose zone: the partially saturated or unsaturated region above the water table that does not yield water to wells; also referred to as the unsaturated zone.

Volatile organic compound (VOC): liquid or solid organic compounds that have a high vapor pressure at normal pressures and temperatures and thus tend to spontaneously pass into the vapor state.

W Waste accumulation area (WAA): an officially designated area that meets current environmental standards and guidelines for temporary (less than 90 days) storage of hazardous waste before offsite disposal.

Wastewater treatment system: a collection of treatment processes and facilities designed and built to reduce the amount of suspended solids, bacteria, oxygen-demanding materials, and chemical constituents in wastewater.

Water table: the underground boundary between saturated and unsaturated soils or rock. It is the point beneath the surface of the ground at which natural ground water is found. It is the upper surface of a zone of saturation where the body of groundwater is not confined by an overlying impermeable formation. Where an overlying confining formation exists, the aquifer in question has no water table.

Weighting factor: a tissue-specific value used to calculate dose equivalents that represents the fraction of the total health risk resulting from uniform, whole-body irradiation that could be contributed to that particular tissue. The weighting factors used in this report are recommended by the International Commission on Radiological Protection.

Wind rose: a diagram that shows the frequency and intensity of wind from different directions at a specific location.

Library Distribution List

Libraries in this list will be mailed a hard copy of this full report (NNSER), a hard copy of the *Nevada National Security Site Environmental Report Summary 2014* (SUM), and a compact disc (CD) containing the NNSER, SUM, and *Attachment A: Site Description*, unless otherwise indicated. All versions are uncontrolled.

Alamo Branch Library, P.O. Box 239, Alamo, NV 89001

Amargosa Valley Library District, HCR 69-2, P.O. Box 401-T, Amargosa Valley, NV 89020

Beatty Library District, P.O. Box 129, Beatty, NV 89003

Boulder City Library, 701 Adams Blvd., Boulder City, NV 89005

Caliente Branch Library, P.O. Box 306, Caliente, NV 89009

Cedar City Public Library, 303 N. 100 E., Cedar City, UT 84720-2610

Delta City Library, 76 N. 200 W., Delta, UT 84624-9440

Goldfield Public Library, P.O. Box 430, Goldfield, NV 89013

Henderson District Public Library, 280 Water Street, Henderson, NV 89015

Front cover photos are prehistoric and historic sites on the Nevada National Security Site (NNSS), which Desert Research Institute (DRI) archaeologists have recorded. DRI implements the Cultural Resources Program to document and preserve cultural resources on the NNSS. (*see Chapter 14 of the NNSSER Section A.5 of Attachment A: Site Description*).

Photos clockwise from bottom right:

Remains of one of many cars from the 1950s staged at atmospheric nuclear test locations in Frenchman Flat. The site, containing other artifacts from testing, is now designated as an historic district.

Historic wood cabin at Cane Spring associated with the 1920s mining town of Wahmonie. Around 1905, the site had been a stop for fresh horses and water for the stagecoach line that brought supplies and people to the Nevada mining towns of Tonopah and Rhyolite from Las Vegas. It is also a recorded prehistoric site used by the Southern Paiute.

Landmark Rock, a prehistoric and historic site within the upper Fortymile drainage system. It is also a significant landscape feature for present day Native Americans.

Entrance to U12e Tunnel at the base of Rainier Mesa. The tunnel was operated from the late 1950s to the 1970s in support of underground nuclear testing.

Historic building at White Rock Springs with corral in the background. The site of White Rock Springs dates from the prehistoric to at least the 1940s.

Prehistoric rock art in Fortymile Canyon (*faded photo behind document title*).
